Water Supplies and Emergency Legislation

THE time honoured adage that It's an ill wind that blows nobody any good may possibly receive a further exemplification of its truth and appositeness if the moral to be drawn from the lesson of the recent drought in Great Britain is brought home to the national conscience Even if it were not a matter of common knowledge and it may be added of harsh experience in many parts of the country the serious admissions and warnings of the Minister of Health during the debate in the House of Commons on April 12 on the Water Supplies (Exceptional Shortage Orders) Bill would be more than sufficient evidence of the unpreparedness of the authorities to cope with a general shortage of water such as is now prevalent and although an endeavour is being made in a nationally characteristic way to muddle through' the emergency the situation is one which cannot be regarded with indifference and unconcern In moving the second reading of the measure Sir E Hilton Young made a scriptural reference to the writing on the wall He could scarcely have chosen an illustration of graver import or more sinister significance

Water is one of the most vital requirements of a community whether for domestic or for industrial purposes In Great Britain happily supplies are as a rule reasonably plentiful in fact their abundance under normal conditions has rendered us oblivious of their value and careless in their use With apparently unlimited resources at disposal consumption has tended to become prodigal and in many cases to be swollen by waste For generations past water supply has been a matter of purely individual or local concern Undertakings have been promoted and administered by private companies and by municipalities without reference to the larger needs and requirements of the country as a whole The number of water undertakings in Great Britain is well over one thousand each of them a separate entity and independent of adjacent concerns, however contiguous the boundaries of their respective jurisdictions In addition there are, at least another thousand private proprietors

Amid all this medley of interests and authorities, apart from the formation within recent years of a few regional committees the functions of which are purely advisory and directed towards the attainment of a common policy among local undertakers there has been no attempt at co-ordination or organised control—nothing beyond the casual supervision of Parliamentary committees at times of legislative enactment for new undertakings and the occasional inquiries of the Ministry of Health or the old Local Government Board when sanction has been sought by local authorities for raising loans for expenditure on works

It cannot be claimed that the country has been taken unawares in the matter, or that the evils of this haphazard procedure have not been pointed out During the last half-century, Royal Commissions and Departmental Committees, as well as scientific bodies, have reported time after time on the need for systematic investigation and administration of the national water resources One outstanding instance is the (1921) Final Report of the Water Power Resources Committee, which contains the following pregnant passage

> "We find that the difficulty in fairly allocating the natural sources of water is becoming greater year by year in England and Wales, and the evidence we have heard proves beyond doubt the urgent necessity in the national interests of some measure of control of all water, both underground and surface, in order that the available supplies may be impartially reviewed and allocated, and may be made to suffice for all purposes in the future In consequence of the increase of population, the improvement in the conditions of life and the growing requirements of industry, the demand for water is steadily increasing, and the problem of meeting future needs is giving rise to anxiety in many parts of England and Wales "

The recommendation is clear and unmistakable Other instances might be cited with equal force It will be within the recollection of readers of NATURE that only last autumn a special research committee of the British Association reported to the meeting at Leicester, after a careful and painstaking investigation extending over a period of twelve months, "that the position of inland water survey in the British Isles is far from satisfactory and that a systematic survey of the water resources of Great Britain is urgently required" The Committee pointed out that the consumption per head of population for domestic purposes has a steady tendency to increase, due to improved standards of sanitation, such as the laying on of piped water supplies into houses in rural areas, the substitution of water-closets for privies, and the provision of baths and hot-water supplies Furthermore, while the amount of water required is increasing and large volumes are being allowed to run to waste, supplies are becoming more and more restricted, the most conveniently situated sources having been to a large extent already appropriated Accentuating the growing paucity of available supplies is the fact, mentioned by Sir Hilton Young, that improvements in drainage have resulted in the more speedy draining away of surplus water and so rendered the effects of a drought more serious It is not perhaps generally realised that the rapid spread of building operations during recent years, more particularly in urban districts, together with road-making, has brought about a considerable extension of the area of impervious surface, causing an appreciable augmentation of the run off after rainfall

The Bill just passed by the House of Commons is merely an emergency measure with the inseparable evils of inconvenience and expense It has been forced on the Government by circumstances and, as such, is simply a temporary palliative and not a permanent cure for a state of affairs which, having risen in the past, is equally likely to recur in the future, if matters are left as they are What is needed, and has been needed all along, is carefully considered legislation on the lines of the Water Power Resources Committee's Report, namely, the establishment of a controlling Water Commission the primary duty of which would be to compile proper records of the water resources and to make provision for the present and future water requirements of the country and, thereafter, to supervise the administration of these resources to the general benefit

At the present time, records of available supplies are sadly incomplete, and an efficient survey is the only means of rectifying the deficiency It is true that excellent records of the incidence and extent of rainfall have been, and are being, kept by the British Rainfall Organization, but this is only part of the scheme of a survey, which, in order to be effective, must cover the whole field of observation from the first arrival of water in the form of rain or dew to its final disappearance into the ocean At present, as is pointed out in the British Association Report, there is no official department dealing with the direct hydrological measurements of the amount of water derived from rainfall, which is the really essential feature of the matter from a utilitarian point of view

Hand-to-mouth methods are out of place in the economy of a properly administered community, and the conditions revealed in connexion with the present emergency should compel the attention of the Government and bring home to it the necessity of taking steps without further delay to inaugurate an adequate service for the scientific measurement and impartial control of the water resources of the country. By so doing, it will bring British water administration into line with the practice in other leading countries, where an example in the matter has been set which can be followed with advantage to everybody concerned.

Faraday's Diary

Faraday's Diary: being the various Philosophical Notes of Experimental Investigation made by Michael Faraday, D.C.L., F.R.S., during the Years 1820–1862 and bequeathed by him to the Royal Institution of Great Britain. Now, by order of the Managers, printed and published for the first time, under the editorial supervision of Thomas Martin. Vol. 3: *May 26, 1836–Nov. 9, 1839.* Pp. xii+466. Vol. 4: *Nov. 12, 1839–June 26, 1847.* Pp. xii+448. (London: G. Bell and Sons, Ltd., 1933.) 7 vols., £12 12*s.* 0*d.* net.

THE printing of Faraday's diary pursues its stately and regular course, and two further volumes are before us covering a productive period of eleven years—from the summer of 1836 to the summer of 1847. Once again we are privileged to toil after the amazingly versatile processes of Faraday's mind. It is the story of much less than a decade which is compressed into some nine hundred printed pages if we bear in mind that the diary is a significant blank between September 1840 and June 1842, and between February 1843 and February 1844. Moreover, when we remember the comparative paucity of the resources at Faraday's disposal and his propensity—indeed a necessity of his nature—to do everything for himself, so that it was impossible for him to depute work of even minor responsibility to a student or assistant, we feel that we have surveyed a record of single-handed achievement of which any great school of research might be legitimately proud. Think of it, Cavendish had, years before, measured specific inductive capacities entirely for his own satisfaction and, *more suo*, had left his results unpublished and unknown to his and to Faraday's generation. It was Faraday's part in this period to rediscover this property and to make those measurements which are quoted and misquoted in most elementary textbooks. Here, too, we find the story of the liquefaction and solidification of various gases by compression and cooling in closed tubes. It is interesting to note—and the remark may bring some small consolation to the amateur glassworker—Faraday's comment on his own glass-bending that "the two bends were not very good; one was a little puckered"; interesting, too, to see that Faraday is consistently faithful to the spelling 'guage'.

At a later date, we have the record of the discovery of diamagnetism, and the immortal entry which runs: "A piece of heavy glass, which was 2 inches by 1·8 inches, and 0·5 of an inch thick, being a silico borate of lead, and polished on the two shortest edges, was experimented with. It gave no effects when the *same magnetic poles* or the *contrary* poles were on opposite sides (as respects the course of the polarized ray) nor when the same poles were on the same side, either with the constant or intermitting current—BUT, when contrary magnetic poles were on the same side, there *was an effect produced on the polarized ray*, and thus magnetic force and light were proved to have relation to each other. This fact will most likely prove exceedingly fertile and of great value in the investigation of both conditions of natural force."

Over and above these prime discoveries and their consequences, we have records of experiments on discharge in air and in gases, on regelation, on electrification by steam and air jets. The effect of lightning on a tree in Greenwich Park is set down, as is an account of the aurora borealis seen at Brighton. The Gymnotus at the Adelaide Gallery is put under observation, and the unhappy animal ("probably very languid, though he gives good shocks when one's hands are well disposed") in the presence of Mr. Bradley, Mr. Watkins and Mr. —— deflected galvanometers, decomposed iodide of potassium and (at a later séance) gave "a spark across a striking distance" and did "burn or deflagrate gold leaves in a very striking and effectual manner".

As in the earlier volumes, so here personal, social and political topics pass unnoticed. A queen comes to the throne; Inigo Jones sets Buckingham Palace in an uproar; the first Education Act is passed; and the voices of the protagonists of the Anti-Corn-Law League are loud in the land. No trace of these alarums penetrates the peaceful atmosphere of the Royal Institution, and the nearest approach to personal gossip is chronicled in the last entry in volume four: "AT OXFORD. Sir William Hamilton and self talked over the relations of two electric currents at right angles to each other when, according to Ampère, they have no mutual action I have expected some effect between them analogous to that state of magnetism which must be the equivalent of static electric induction, but could never discover any Sir William Hamilton, I find, expects an effect on mathematical principles Must try again in various ways"

The scientific world is heavily indebted to the managers of the Royal Institution and to Mr Martin, and it were an ungracious task to seek to increase that debt In publishing the "Diary" they are indeed raising to the memory of Faraday a monument more enduring than brass But how much more noble would be the monument were it completed by a similar worthy edition of Faraday's works and his letters, and crowned by that critical biography, of which science and letters still stand in need ! ALLAN FERGUSON

Industry and Leadership

Management of Tomorrow By L Urwick Pp xvii+205 (London Nisbet and Co, Ltd, 1933) 8s 6d net

THERE are few graver problems that confront industry and society alike than that of securing competent leadership under the difficult conditions of our time Important attempts have been made at training for management as exemplified in the Department of Business Administration at the London School of Economics, or the Institute of Industrial Administration, as well as in the courses in industrial administration arranged by the College of Technology, Manchester, but hitherto industry as a whole has made little use of such experiments, nor can it be said that it has given the matter the systematic study and attention which it deserves

On the reasons for this position Major Urwick's thoughtful and stimulating book throws a flood of light Despite the voluminous literature in this field of the last thirty or so years, he makes a definite contribution to management literature which commands attention by the vivacity of its style as well as by the clarity of its thought Discussing first the scientific approach to business management, Major Urwick suggests that what is required is the application of the scientific method of thought to economic activity, as it has already been applied to a large extent on the production side He has a wide and well-balanced conception of management as a science in which an analysis and a basis of fact is substituted for opinion to the limits of our power and knowledge The book abounds in shrewd observations which deserve to be pondered by all who hold or aspire to, administrative responsibility

The mere review of the field of management which Major Urwick supplies in brief compass is in itself challenging, and reveals how much might be done to remove causes of industrial friction and inefficiency This is notably true of research into management problems where Major Urwick does much more than emphasise the opportunities for co operation between different industrial units and industries or the value of what are known as management ratios He directs attention to the growing influence of professional ideals in industry and their power to stimulate such research, as well as to the way in which the elucidation of the principles which should govern the administration of large scale combinations would assist in their efficient administration even without organising genius

On such matters as organisation and distribution, Major Urwick writes in a way that should arrest the attention of scientific workers, noting, for example, how industry has yet to utilise the store of experience of organisation acquired by military institutions or the Church, as well as presenting a highly suggestive programme of market research worthy of the attention of all concerned with distribution In dealing with this difficult field, he conveys a clear conception of what rationalisation really is, as well as exposes some of the muddle headed thinking which has foundered a good deal of industrial enterprise, large and small

If, in this section of his book, Major Urwick gives us a hopeful picture of the possibilities which may attend the application of scientific thought to the problems of distribution, the section on training for management will probably be that most appreciated by scientific workers Whether discussing the training of foremen and supervisors or of administrators, Major Urwick has a keen eye for essentials He reveals the defects of our present lack of system, our failure to grasp that, in education of foremen, leadership and co-operation are the only two ends which matter, and adds one more powerful plea for industry to consider just what it demands of its leaders and recruits and to co-operate with educational authorities to secure an adequate supply of the requisite quality

No part of the book is indeed more thought-provoking than this Major Urwick emphasises industry's responsibility for collaboration in completing the training of its recruits, he directs attention to the dangers of departmentalism and suggests that the naval and military practice of requiring those aspiring to high command to devote one or two years to advanced theoretical work at a staff college at an intermediate stage of their career might be studied in industry Courses of instruction in industrial administration may well find their natural place in industry at some such stage as this Major Urwick's most readable book abounds in constructive suggestions for the utilisation and development of that capacity for leadership in the best sense which is too rare and valuable to be neglected wherever found R BRIGHTMAN

A Digest of Clinical Medical History

A Short History of some Common Diseases By divers Authors Edited by W R Bett (Oxford Medical Publications) Pp vii+211 (London Oxford University Press 1934) 10*s* 6*d* net

SOMEONE has said that to know the history of a subject is already to know more than the half of that subject, or words to that effect Mr W R Bett, formerly honorary secretary of the Section of the History of Medicine, Royal Society of Medicine, has saved all future inquirers into the development of knowledge regarding common diseases a great deal of labour by editing the volume just published Each chapter is written by a different author, someone specially qualified to write on the subject assigned to him, as the following list of contents will show —Acute infectious diseases by Sir John Broadbent, Bt tuberculosis by Prof John Fraser, venereal diseases by Sir D'Arcy Power, pneumonia by E M Brockbank, rheumatism by F J Poynton, rickets by Leonard Findlay, endocrine disorders by Sir H Rolleston, Bt, Bright's disease by Prof J A Nixon, heart disease by Robert O Moon, epilepsy by James Collier, arthritis by John D Comrie, gall stones by Prof D P D Wilkie, tonsils and adenoids by Lionel Colledge, malignant disease by Harold Burrows, and malingering by Sir John Collie

Mr Bett assigned to himself the subject of appendicitis, though, in truth, he might have taken any of the other topics under his wing, of whose quills for literary purposes he has an inexhaustible supply.

It is an immense convenience to be able to have condensed within the compass of a few pages, in each case respectively, a complete synopsis of the references to a disease or a function from the earliest mention to the present day

The essays on rickets, epilepsy, gall stones and malignant disease may be singled out for special praise Much of the ground traversed in these articles is far from the beaten tracks of medical history, and they must assuredly have given their authors no little trouble to compose

Sir Humphry Rolleston's chapter is characterised by a meticulous regard for the earliest occasion on which a particular term was used, and it is conspicuously well provided with dates and with the Greek roots of physiological and medical terms Amongst many other things, we learn from this valuable summary of knowledge that Pierre Marie, who first described acromegaly, is now eighty one years old and that the status lymphaticus is no longer considered to be a pathological entity

Some of the chapters bring home to us vividly the unsatisfactory nature of our knowledge concerning the real source or cause of certain common clinical conditions for example rheumatism The absence from this discussion of the rheumatic diseases of the name of R Llewellyn J Llewellyn is difficult to understand Llewellyn, the writer of widely known works on rheumatism, arthritis, gout and fibrositis is an authority of international reputation who has lately introduced the vitamin cum sunlight deficiency theory of rheumatic conditions Dr Poynton does not once quote from him nor does Dr Comrie in his chapter on 'Arthritis" What is still more inexplicable is that Llewellyn's name is omitted from the index, otherwise a very full one As is right, Llewellyn is quoted on Malingering

Further, when lactic acid as a possible factor in the etiology of rheumatism is being referred to (p 66), no mention is made of the late Dr Percy Wilde of Bath, who devised a valuable 'pyretic couch' for the cutaneous elimination of the (hypothetical) lactic acid

On page 148, and again in the index, the name of Vallisnieri is misprinted

The statement on p 192 that Galen in *1538* narrated the instance of an orator who simulated an attack of colic to avoid making a speech is interesting in more ways than one Either the date should be A D 153 or Galen is, in a certain sense, still with us D F. F-H

The Genus *Lilium*

A Supplement to Elwes' Monograph of the Genus Lilium By A Grove Part 1 Pp v+viii+12+4 plates (London Dulau and Co, Ltd, 1933) 52s 6d

NO more worthy memorial to the late Henry Elwes could have been devised than the magnificent supplement to his monumental "Monograph of the Genus *Lilium*", the first part of which has just been published The supplement has very wisely been produced in the same form as the original monograph, published in 1880, and the plates by Miss Lilian Snelling are as faithful and as well reproduced as could be desired

Dame Alice Godman, who is responsible for the publication of this supplement points out in her foreword how fortunate it is that Mr Grove who had collaborated with Mr Elwes in the preparation of material for such a supplement, has been able to carry out the work to completion

Botanists and horticulturists alike join in congratulations to Mr Grove, who modestly quotes the words of Elwes in the first paragraph of his introduction, and applies them to himself, but they will not allow that these really apply to Mr Grove, who has devoted so many years to a detailed study of the lilies, and as a result of careful work is now rightly regarded as an authority on the genus

The supplement is to be issued in six or seven parts, and this first part contains a very informative introduction by Mr Grove—unfortunately on the dedication page his Christian name is given as Alfred instead of Arthur—in which he gives many interesting historical facts in addition to much valuable botanical information

Then follow the four plates included in this first part *Lilium Sargentiæ* Wilson, from Western China, with its lovely funnel shaped, pinkish white flowers, which are rosy purple on the outside—one of the few species which bear bulbils in the leaf axils, *Lilium Henryi* Baker with its orange coloured, nodding flowers with recurved petals—a species found in the Ichang Gorges, Central China, by the late Prof Augustine Henry, *Lilium rubellum* Baker, the lovely rose petalled lily from Japan, and *Lilium cernuum* Komarov, from Korea and Manchuria distinct among lilies for its nodding lilac coloured flowers and numerous linear leaves

The fine plates are accompanied by full descriptions both in Latin and in English and following these Mr Grove has given a very complete and lucid account of our knowledge of these lilies and the history of their introduction to cultivation

---

Short Reviews

An Introduction to the Study of Map Projections By J A Steers Third edition revised and enlarged Pp xxiii+227 (London University of London Press Ltd, 1933) 8s 6d net

MR STEERS's useful little book on map projections, the third edition of which has recently been issued, is written for those students of geography who have only the most elementary knowledge of mathematics, and avoids all analysis and any mention of the calculus Subject to this self imposed limitation, the author succeeds, in general, in presenting to the beginner an accurate view of most of the useful projections, with some outline of recent work in this field of study The illustrations are good and some are ingenious, notably the plate showing a comparison of five zenithal polar projections The third edition differs from the second chiefly in the addition of two new chapters, one dealing with Col Craster's parabolic projection of the whole sphere and with related projections, and the other describing briefly some other new, or unusual, projections, such as Craig's retroazimuthal group, or Maurer's orthodromic or two point azimuthal projection

The method of presentation is most successful in describing the zenithal and conical groups and equal area world maps such as Mollweide's It is, of course least happy in dealing with Mercator's and other orthomorphic projections There are a few expressions which might be corrected in a fourth edition on page 5 it is stated that 'the azimuths will coincide with the meridians', and on page 110, with reference to Mercator's projection there is the remark that the sum of the secants from the Equator to that parallel must be found' The note on page 2 wrongly includes Fig 16

The book is well got up and is amply illustrated by plates and diagrams, the issue of a third edition within six years of the first publication, shows that there was an undoubted need for a book of this type and that it does meet the requirements of the non mathematical geographer

Reports of the Progress of Applied Chemistry Vol 18, 1933 Pp 770 (London Society of Chemical Industry, 1933) 12s 6d, to Members, 7s 6d

THIS important annual volume is modelled on the familiar plan of the series and fully maintains the customary high standard Not only is it almost indispensable to workers in the domain of technological chemistry, but also it offers to other scientific workers, and indeed to many whose work is not scientific at all, an excellent review of progress in one of the greatest of the world's industries The opening paragraphs of the chapter on fuel, for example, show how the chemist, in effecting economies and developing alternative sources, is quickly brought into contact with reverberations in the form of social problems and the incidence of taxation It is satisfactory to read that precautions taken in British gas works in regard to waterless gasholders are adequate to prevent another such disastrous explosion as that which occurred in Germany at Neunkirchen

In the chapter on textiles, reference is made to the ignorance displayed by the general public including some newspapers, about the conduct of the chief manufacturing industry of Great Britain, this industry is engaged in a struggle of serious national significance, and appreciation of its position can be based only on knowledge of its mode of existence Fortunately, in certain other branches of chemical industry, steady improvement is reported Thus in the iron and steel industry there is "quiet optimism", in the glass industry "improving tendencies , in the rubber industry ' encouraging aspects ' despite instability, in the leather industry improvement" The report on the food industry refers with concern to the unpleasant fact that a very large proportion of the world's inhabitants are seriously undernourished, and indicates the chemist's part in remedying this state of affairs But a few references such as these cannot adequately reflect the interest which the report provides A A E

Technique of Modern Welding By Prof P Bardtke Authorized translation from the second German edition, with additions and revisions by Prof Bardtke, by Harold Kenney Pp xi+299 (London Glasgow and Bombay Blackie and Son, Ltd, 1933) 15s net

IN recent constructional engineering there has been no more notable development than the application of welding Welded joints, to day, are used in bridges, boilers, ships, roofs, motor cars, aeroplanes and many other structures At first carried out by rule of thumb methods, a rational technique has been developed, symbols and codes have been introduced, standardised tests established and there is already an extensive literature on the subject To this literature this translation of a book by the works manager of one of the German State Railways is a valuable addition The main chapters deal with fusion welding, pressure welding, the applications of welding and the economics of welding There are also chapters devoted to testing, to accident prevention and to gas cutting Descriptions of the various types of plant are included and many useful hints are given on the welding of both ferrous and non ferrous metals The book is well printed and illustrated and contains an adequate index

Outlines of Organic Chemistry a Book designed especially for the General Student By Prof F J Moore Revised by Prof William T Hall Fourth edition Pp xiv+338 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd 1933) 16s 6d net

THIS book was written merely to serve as an introduction to organic chemistry and to serve as a guide especially to those who study the subject from a non professional point of view" It provides a coherent and straightforward treatment of the subject but considering the particular aim in view it is remarkable that the work conveys no sense at all of the historical or chronological development of the subject The account is formal and singularly impersonal so that for example, the fundamental account of stereochemical theory contains no mention of Pasteur Le Bel or van 't Hoff The experimental aspect of organic chemistry also receives little attention The book is well printed but sparsely illustrated British students will consider it expensive J R

The British Journal Photographic Almanac and Photographer's Daily Companion, with which is incorporated The Year Book of Photography and Amateurs Guide and The Photographic Annual 1934 Edited by George E Brown Pp 684+64 plates (London Henry Greenwood and Co Ltd 1934) 2s net

THIS almanac has been published as a book since 1861 Mr Brown has edited it since 1906 Year by year he has made it a very worthy daily companion for the photographer While it contains, in each issue brief working details of most of the common processes of photographic technique, it seems to keep thoroughly up to date By means of good indexes, which cover advertisements as well as text it has been possible to make the long series of volumes into a kind of encyclopædic work from which not only details of technique may be learned, but also the development of photography may be followed It can be recommended confidently to all who use photography

Das Problem der Gleichzeitigkeit Von Dr Karl Vogtherr Pp 196 (München Ernst Reinhardt 1933) 5 50 gold marks

ALL who desire to acquaint themselves with the attitude of a serious and well informed critic of relativity theory from the philosophical point of view may be recommended to read this book The author examines the postulates and axioms of geometry, time theory and kinematics, and the principles underlying measurements of space, time and motion and then discusses the determination of the simultaneity of events Although his conclusions are certain to be challenged by geometers and relativists alike, nevertheless his book will be found very interesting and stimulating, whatever may be the reader's opinions on the many contentious questions raised in it

Lord Avebury (1834–1913)

THE centenary of the birth of Sir John Lubbock, afterwards Lord Avebury, occurs on April 30 and the occasion should not be allowed to pass without grateful tribute to his memory. It is perhaps difficult for the younger generation to realise the distinguished position which that great Victorian held in the scientific world of his day. In the present era of specialisation many may underrate the claims to greatness of one who was an amateur naturalist and a popular writer. But a more careful consideration of his work and aims will show that he helped to lay those foundations of science and scientific education which has given the present generation of professional scientific workers the opportunities they now enjoy.

We must remember that in the days when science was not included in the ordinary school curriculum and was a negligible part of a university education, the advance of science was largely due to the work of amateurs, such as Charles Darwin, Sir John Lubbock the banker, Sir Joseph Prestwich the wine merchant, and Sir John Evans a paper manufacturer. Not that there was anything amateurish in the work of these pioneers. They were capable of intensive and fundamental researches and Lord Avebury's 'Monograph on the Collembola and Thysanura", published by the Ray Society, is sufficient proof of his capacity for thorough and detailed investigation, and will remain an authoritative and standard account of these groups of insects. It was the wideness of his interests, and not any lack of thoroughness, which both prevented Lord Avebury from continuing his researches in one branch of science and at the same time caused him to become an all round naturalist of remarkable attainments.

Lord Avebury's love of natural history dated from his infancy, and his mother, who for many years charged herself with his education, noted in her diary that his taste for natural history made him an acute observer. His father, an able mathematician and a fellow of the Royal Society, took an equally careful share in the early education of his son, and when the latter was at Eton repeatedly urged the authorities to include some science in the curriculum. Both parents had very definite views on education, and dissatisfied with John's progress at Eton, he was withdrawn at the early age of fourteen and a half and at fifteen years of age began life in the family bank, of which he became afterwards the head. But in spite of the exacting commercial duties, by working early and late, throughout his long business career he devoted himself to the acquisition of new knowledge, both literary and scientific. Thus, though Lord Avebury never went to a university, he acquired a wide culture and a deep insight into Nature. Living in the country and being a keen observer he devoted himself wholeheartedly to the study of botany and entomology. His residence at Down gave him the inestimable advantage of a close personal intercourse with Darwin, who appreciated the ardent and inquiring mind of his young friend and always held him in high esteem. There is no doubt that Darwin's kindly help was a great stimulus to young Lubbock, who frequently expressed his gratitude for the inspiration he received from Darwin. That he became one of the staunchest supporters of the 'Origin of Species' is not to be wondered at, and Darwin valued his support, for writing to him in 1860 he says: "I settled some time ago that I should think more of Huxley's and your opinion, from the course of your studies and from the clearness of your mind, than that of any other man in England".

It was Darwin who urged Lord Avebury's father to get his son a microscope, with the help of which his earliest researches on freshwater and marine Entomostraca and on *Daphnia* were carried out. On the strength of these investigations Lord Avebury was elected to the Royal Society in 1858 at twenty four years of age. With the encouragement of Darwin and Huxley he commenced his investigations on insects, which he carried on for many years and which culminated, after a series of important papers, in the publication of the monograph of the Collembola already referred to, and of two books, one on "The Origin and Metamorphoses of Insects" and the other on "Ants, Bees and Wasps". His work on the senses and habits of these insects was based on definite experiments and on observations carried out for many years in succession on ants imprisoned in earth between glass plates. His own observations on the habits of insects, and the stimulus of Darwin, who was engaged in his studies of self and cross fertilisation of flowers, directed Lord Avebury's attention to the visits of insects to flowers, which resulted in the publication of his 'British Wild Flowers considered in Relation to Insects". This was the commencement of a series of botanical books on "Flowers, Fruits and Leaves", on "Buds and Stipules", and lastly the comprehensive "Contribution to our Knowledge of Seedlings". In all three books he showed a keen insight into the morphological problems involved, and they will continue to be of the greatest help to botanical students.

Long before he had completed his entomological and botanical researches, Lord Avebury's active mind had been turned for a time into other channels, and his intimacy with Galton, Prestwich and John Evans had directed his thoughts to problems connected with the antiquity of man. A series of visits to France, Denmark and Switzerland gained him a sound and extensive knowledge of prehistoric mounds and implements which enabled him to become one of the leaders of anthropological research in Britain, as his "Prehistoric Times" and "The Origin of Civilisation and the Primitive Condition of Man" amply testify. Anthropology, indeed, became an abiding interest with him, and he did much to preserve the destruction of prehistoric remains by introducing into Parliament the Ancient Monuments Act of 1882. It is largely due to his energy and foresight that the monumental stone circle at Avebury was preserved from further destruction, and it is characteristic of his deep interest in the latter, that when he was elevated to the peerage he took the name of Lord Avebury.

For most business men, three absorbing hobbies, including the writing in connexion with them of important books, which ran into many editions, would have been more than sufficient to occupy their time and energy, but from boyhood Lord Avebury made systematic use of his time and worked early and late to forward the aims he had set before himself. Thus, when invited to become a candidate for Parliament he accepted the invitation, much to the dismay of Darwin and Hooker. The latter wrote to Darwin: "I gnash my teeth when I think of Lubbock going into Parliament. I grudge so good a man from Science." Darwin, who had been reading Lubbock's "Prehistoric Times", wrote to congratulate him on the book, and added: "I do sincerely wish you all success in your election and in politics; but after reading this last chapter you must let me say: Oh dear! Oh dear! Oh dear!' "

Lord Avebury had, however, set himself several definite aims as Member of Parliament. They were: to carry a measure to prevent a rapid destruction of ancient monuments, to promote the study of science in schools, to secure some additional holidays and to shorten the hours of labour in shops. We have seen how successful he was in the first of these aims. The others he was happily destined to see eventually realised. A year after entering Parliament he was successful in getting the Bank Holidays Act. How many, we wonder, of those who have recently enjoyed the relaxation of a fine Easter Monday realise to whom they owe this boon. His warm heart for those less favourably placed than himself led him to introduce successively and successfully the Shop Hours Regulation Act of 1886, limiting the hours of labour of young persons under eighteen years of age, an Open Spaces Act, a Public Library Act and a Shop Hours (Early Closing) Act. His effort to promote the study of science in schools did not lead to the promotion of any parliamentary measure, but nevertheless his persistent agitation led to the appointment of several Royal Commissions dealing with educational problems of elementary schools, public secondary schools and the universities.

On all these Commissions Lord Avebury voiced the growing need of scientific training, and there is no doubt that many changes in this direction resulted from the evidence given and the reports of the Commissions. Particularly in relation to the Royal Commission on Scientific Instruction at the Universities, the Commission recommended substantial capital as well as annual grants towards the cost of maintenance of the universities, and the grants now given by the Treasury to the universities may be traced to the report of this Commission and to the persistent efforts of Lord Avebury. By his numerous scientific publications on anthropological, entomological and botanical subjects he did much to diffuse an understanding and love of science among the general public, and the widespread interest which he created can be gathered from the numerous editions, often reaching double figures, which were called for. His energy in this respect was ceaseless. Darwin wrote to him once: "How on earth you find time is a mystery to me". But his business had made him methodical and he knew how to economise his time. Once when remonstrated with by his family for wearing elastic sided boots, he explained that one could learn a language in the time people took to button or lace their boots.

Lord Avebury felt driven to write and publish both his scientific and also his more popular books because of the intense enjoyment he personally got out of all his studies and of his keen desire that others should share in his pleasures. Even at home, when he had prepared a particularly good microscopic slide, he delighted to show it to the inmates of his house, including the maids and the page boy. No one had a keener appreciation of natural surroundings, and he desired that the minds of others should be awakened to this. Hence his publication of "The Beauties of Nature" and "The Wonders of the World we live in". Similarly in "The Scenery of Switzerland" and "The Scenery of England" he explained how it was based on the geology and physical geography of these countries. Lord Avebury had also a real love of good literature, and after addressing the Working Men's College on "The Choice of Books" he published his essay on "The Hundred Best Books" which excited much interest and comment and resulted in the publication of cheap editions of many books which were out of print. His aim was ever to promote the national culture of his fellow citizens. He wanted the general public as well as the schools to enjoy a stimulating intellectual atmosphere "charged with the oxygen of science", as Sir Michael Sadler has so aptly put it. It may truthfully be said that he succeeded in a great measure in effecting this by his personal efforts. The ever present benevolent urge combined with the simplicity and modesty of his bearing made him a most lovable character. The contentment of his life so full of good deeds, radiated a serene charm, which was felt by all with whom he came in contact. Scientific societies and educational institutions were eager to secure his services, and he probably held a record number of presidencies of learned societies and scientific institutions.

It is not possible within the limits of an article such as this to do more than touch upon some of the activities of so many sided a man Happily there is a good biography of him by H G Hutchinson and The Life Work of Lord Avebury edited by his daughter the Hon Mrs Grant Duff contains appreciations of his work by leading authorities of the various branches of science which Lord Avebury has enriched by his researches and publications When reading these we shall gratefully remember how much we owe to this great Victorian naturalist F E W

Stabilisation of Radio Frequencies

AMONG the problems which the rapid and extensive growth of radio communication has presented is that of keeping the frequencies of all transmitting stations steadily at their assigned values The success of the various international plans which have been formulated in recent years particularly for the control of broadcasting must ultimately depend upon the ability of radio engineers to adjust and maintain a wireless transmitting station at its correct frequency or wave length At the present time the primary standards of frequency which utilise either a tuning fork or a piezo electric crystal are amongst the most accurate of our physical standards With the aid of suitable equipment there is no difficulty in maintaining and using an accuracy well within one part in a million while the frequency standards of different countries are in substantial agreement to within a few parts in ten million Similar types of crystal or tuning fork oscillators can be employed to control the frequency of transmitting stations of appreciable power by the aid of somewhat elaborate power amplifying and if necessary frequency multiplying equipment This arrangement admirably serves the purpose of those stations operating on a single wave length and is used with conspicuous success in broadcasting stations and those used for long distance telegraphic and telephonic communication

There are however many cases particularly in connexion with ship and aircraft communication where it is necessary that the transmitting station shall be able to operate on a large number of different wave lengths and still maintain a high degree of accuracy and stability on each of these wave lengths It is usually an accompanying condition of such circumstances that the whole of the transmitting and frequency controlling apparatus must be much simpler than that which is employed at fixed land stations It is to meet such a demand as this that the Radio Research Board of the Department of Scientific and Industrial Research is at present studying the problem of developing a suitable valve oscillator which will provide frequency stability at a transmitting station without the necessity for elaborate equipment

As a preliminary to the experimental work which is now being conducted by the Radio Department of the National Physical Laboratory a thorough survey of the available information on the subject was made and this has recently been published* This résumé of the literature has been drawn up in two parts The first part consists of an essay on the subject as a whole and comprises in effect a brief textbook of the fundamental principles of this branch of radio science illustrated by reference to typical circuit arrangements used in practice The second part consists of abstracts of papers representative of the most important published work on the subject with commentary notes which are intended to bring each particular contribution into perspective with the whole

In attempting to classify the causes of frequency variations in simple valve maintained oscillators a distinction can be drawn between frequency variations due to changes of a purely electrical character and those due to changes of the physical configuration of the system A simple and admittedly inadequate analysis of the valve maintained oscillator indicates that frequency variation due to incidental changes in the valve and its circuits can be minimised by meeting certain conditions Various special circuit arrangements have been developed on these lines and the consequent frequency stabilities obtained are variously estimated at between one and one hundred parts in a million A more exact analysis shows that it is very difficult to maintain electrical oscillations by means of a valve without producing harmonics which have a detrimental effect upon the steadiness of the fundamental frequency Experimental data are lacking as to the quantitative significance of this effect which however may be minimised by means of circuits designed to reduce so far as possible the potential differences due to the harmonics generated Recent investigations have shown that the inter electrode capacitances of thermionic valves may be expected to vary with the space charge conditions of the valve which in turn will vary with supply voltage and oscillation conditions Since these inter electrode capacitances are included in the electrical circuit which determines the frequency of oscillation any variation in this capacitance will produce a corresponding variation in the frequency

An ideal valve oscillator is probably one in which the frequency of oscillation is determined solely by the inductance and capacity in the external oscillatory circuit In this case however it is evident that the frequency will be directly dependent upon any changes in the physical configuration of this circuit due to changes in atmospheric conditions. For example, changes in temperature of the inductance coils and condensers in the circuit will produce changes in the electrical values of these components to an extent depending upon the coefficients of expansion of the materials used in their construction. The limited experimental evidence so far available indicates that changes of frequency resulting from temperature variations may exceed fifty parts in a million per degree centigrade. To a lesser, but by no means negligible, extent, changes in atmospheric pressure will produce a change in capacitance of an air condenser by virtue of the alteration in the dielectric constant of air. A further factor to be taken into account in a complete study of the subject is the effect of the load circuit, which is coupled to the oscillator and by means of which the oscillations generated are put to practical use. A brief consideration of the relevant conditions indicates that in order to minimise the effect of the load circuit on the oscillation frequency, this circuit should be slightly detuned by an amount which depends upon its effective resistance.

---

* Department of Scientific and Industrial Research. Radio Research Special Report No 13 Valve Oscillators of Stable Frequency a Critical Survey of Present Knowledge By F M Colebrook Pp vii+56 (London H M Stationery Office 1934) 1s net

In conclusion, the possibility of securing frequency stability in radio transmitting stations by the use of an automatic monitoring arrangement is discussed briefly in the report recently published. The scheme provides for the frequency of the transmitter to be adjusted directly to agree with that of a small power valve oscillator designed for a high-degree of frequency stability under no load conditions. If such a scheme can be developed successfully without undue complication of equipment, it may provide one solution to the problem of stabilising the frequency of a simple transmitter which has to be operated over a wide range of frequencies. The whole subject is, however, being investigated in a comprehensive manner, since more than one solution may ultimately be necessary to meet the conditions of practical radio communication.

Physiology of the Blue Whale

By Prof. AUGUST KROGH, Laboratory of Zoophysiology, University of Copenhagen

RATE OF GROWTH

IN the paper by Mackintosh and Wheeler, "Southern Blue and Fin Whales" ('Discovery Reports", I 1929), a graph is given showing the growth in length of the Blue whale from the fœtal state to maturity. In Laurie's paper, "Some Aspects of Respiration in Blue and Fin Whales" ("Discovery Reports", VII, 1933), graphs are given showing the relation between length and weight of Blue whales, and since this relation is remarkably constant, it becomes possible to calculate the weight of the young whales at different stages.

Such a calculation shows the new born Blue whale of 7 m. length to weigh about 2,000 kgm., while at weaning seven months later, the length has increased to 16 m. and the weight to 23 000 kgm. When the whales become sexually mature at two years of age, the females are on an average 23·7 m. in length and weigh 79,000 kgm. The period from weaning to maturity includes two summer seasons (about twelve months) in antarctic waters with abundant food, and one winter in more northern waters where food is scarce. The increase from 23,000 kgm. to 79,000 kgm. therefore takes place mainly or exclusively during the twelve months when they are in the antarctic. Laurie gives a table showing the composition of a 20 m. Blue whale. Assuming the same composition during the period of growth, the 56,000 kgm. increase should be distributed as follows:

			Fat		Protein	
	per cent	kgm	per cent	kgm.	per cent	kgm
Meat and entrails	59	33 000	6 5	2,150	23	7 600
Blubber	18 6	10 400	88	9,200	4	400
Bones	19	10 600	45	4 750		,
		54 000		16 100		8,000

Calories 150 mill. + 44 mill. = 194 mill.
Calories per day in 365 days = 540 000
" " 518 = 380 000

It may be of some interest to compare this rate of growth with that of a pig. The new born pig weighs about 1 kgm. After seven weeks' lactation, the weight is about 6 kgm. and, feeding with about 200 kgm. of skim milk and 300 kgm. of grain, it attains the weight of 90 kgm., at which it is converted to bacon at the age of six months. The food consumed corresponds to a little more than 1 million calories, and the increase in weight from weaning to 320,000 calories, or 2 600 cal. per day. Assuming an average weight for the growing pig of $\frac{6 + 90}{2}$ = about 50 kgm. and for the growing whale of $\frac{23\,000 + 79{,}000}{2}$ = about 50 000 kgm., it is seen that the growth of the pig per unit weight is about five times as rapid as that of the whale. The comparison should not, however, be made on the weight but on the surface basis, corresponding to the cube root of the square of the weight ($W^{2/3}$). When the whale weighs just 1,000 times the pig, the increase per day should be $1{,}000^{2/3} = 100$ times as large, but it is found to be 540,000 calories instead of 260,000, or just double that of the pig, in spite of the fact that the pig has its food served regularly, while the young whale is left to its own resources. It is a pity that the chemical composition of the crustacean *Euphausia superba* constituting the whales' staple diet is not known. It would be extremely interesting to know if whale fat is mainly derived directly from the food or mainly built up by synthesis.

METABOLISM, CIRCULATION AND RESPIRATION

On the assumption that the surface law is valid for whales and that the normal metabolism is

1,000 calories per sq m per day, Laurie arrives at the figure 275,000 calories as the resting metabolism of a 122,000 kgm Blue whale It is worthy of note that the assumption, for which good reasons are given by Kleiber ('Die Tierernährung", 5, 1933), that metabolism is proportional to $W^{3/4}$ instead of $W^{2/3}$ with a unit value of 72 cal per day, would raise the calculated metabolism to 460,000 cal It might, I think, be possible to arrive at a value for the metabolism by calculating the heat loss from an internal temperature of 35° C, a water temperature of say 5° C, measurements of the thickness of blubber and its properties as a conductor of heat A series of temperature determinations through the thickness of blubber of a freshly killed whale would enhance the value of such a determination

The metabolism of a whale is increased by its muscular movements in swimming Prof Carl Hansen, of the Danish Technical High School, has kindly calculated for me the towing resistance at various speeds of a 122,000 kgm whale, the surface of which he calculates as 230 m^2 He finds the resistance and horse power necessary at different speeds to be as shown in the accompanying graph (Fig 1) where *R* represents the resistance in kgm and *N* the necessary horse power At 3 knots the necessary power is 1 5 h p, at 5 knots it is 6 5 h p and at 10 knots 46 8 h p He assumes 100 per cent efficiency as a propeller for the tail, which he believes to be superior to any screw If I assume a 22 per cent efficiency for the muscular engine working the propeller, I find as a good approximation 10 litres of oxygen or 50 calories consumed per h p per minute It would be of great interest to have actual determinations of the towing resistance of whales at varying rates of speed, and it should not be very difficult to obtain such figures

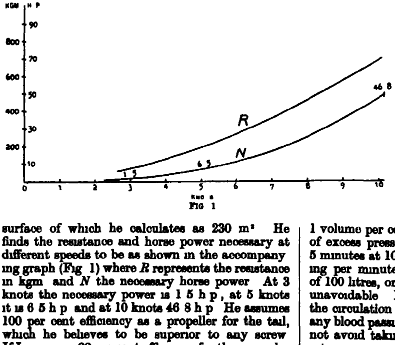

FIG 1

The assumed resting metabolism of 275,000 calories per day corresponds to 38 litres of oxygen per minute Assuming that the whale swims at an average rate of only 3 knots, we have a total metabolism of 53 litres of oxygen per minute We may suppose in the case of this whale, in accordance with the findings on man and other mammals that, at rest, about 40 per cent of the oxygen capacity (14 volumes per cent) of the blood is utilised, which gives us a circulation rate of very nearly 1,000 litres per minute A Blue whale can swim at the rate of 10 knots when harpooned This means a metabolism of a little more than 500 litres of oxygen per minute With such heavy work the oxygen utilisation may reach 80 per cent and the circulation rate would become 4,500 litres per minute

The capacity of the lungs is estimated by Laurie from their weight at the very small figure of 3,050 litres A better approximation is obtained by measurements of the thorax volume, subtracting the heart, and the weight of the lungs For a whale of 22 m this was estimated at 7,000 litres and I arrive at 14,000 litres as the most probable figure for the 27 2 m whale Careful measurements of the thorax volume of whales are among the chief desiderata for physiological calculation 14,000 litres of air would provide the whale with approximately 2,800 litres of oxygen or enough for 50 minutes at the estimated metabolism of 53 litres per minute

Because the possible thorax volume is evidently approximately proportional to total volume or weight of animal, while metabolism is proportional to some fractional power of the weight (probably between $W^{2/3}$ and $W^{3/4}$) large size is essential for the capability of prolonged diving

LIABILITY OF WHALES TO CAISSON DISEASE

In deep diving, the blood passing through the lungs becomes supersaturated with nitrogen About 1 volume per cent is taken up for each atmosphere of excess pressure Supposing the whale to stay 5 minutes at 100 m, the 1,000 litres of blood passing per minute would take up an extra amount of 100 litres, or 500 litres in all This is, I believe, unavoidable It seems to me inconceivable that the circulation should stop during deep dives, and any blood passing through the lungs could certainly not avoid taking up the corresponding volume of nitrogen

A slow circulation will reduce the rate at which nitrogen is absorbed, and to that extent large size is advantageous, but it will reduce also the rate at which the gas is given off at lower pressures Supposing the whale to take a series of dives to 100 m, staying at the surface each time only for the few seconds necessary to take one or two breaths, a progressive supersaturation of the blood and the tissues seems unavoidable, and, should the whale choose to stay at the surface for some time afterwards, nitrogen bubbles should appear both in the blood and in the tissues—in other words, the whale would be liable to a severe attack of caisson disease

The striking evidence presented by Laurie shows (to my mind conclusively) that serious supersaturation of tissue fluids with nitrogen does not supervene, but just how it is avoided is by no means clear Laurie has made the remarkable discovery of the nitrogen binding *X* organisms in the blood of whales, but, admitting everything he claims for them, their nitrogen fixation is far too slow to be an essential factor, the more so as the fixation requires oxygen, and in all probability not less and probably more than 1 volume for each volume of nitrogen The 100 litres assumed to be absorbed per minute at 100 m would therefore require 100 litres of oxygen, or almost double the volume necessary for the whale's metabolism proper This, I think, is outside practical possibilities

I suspect that the retia mirabilia of blood vessels present in all deep-diving mammals may have something to do with the mechanism for escaping caisson disease, but I must confess my inability to see how I suggest, however, that our knowledge of these structures, in spite of the valuable anatomical research done upon them, is too incomplete to make speculation worth while, and would point out that a detailed and also quantitative investigation of the retia is highly desirable

Obituary

Mr William Barlow F R S

WILLIAM BARLOW was born in Islington, London, on August 8, 1845, and inherited from his father, Frederick Barlow, a business dealing with estate and building property, by the exercise of notable acumen in affairs he realised the business and thus found himself early in life possessed of ample means Barlow was educated privately, he had a taste for physical science and marked mathematical talent, but cultivated the latter unsystematically and perhaps almost exclusively

Barlow thus found himself in his early thirties with an independence, with a genius for handling geometrical problems of a particular kind and with ample leisure to devote to the study of crystal structure, which had become the subject of his choice He had not, however, received that rigid disciplinary training through which most students of physics and chemistry acquire a broad sense of contemporary knowledge of the physical universe In some respects this was a hindrance but in others an advantage, it left a powerful intellect unhampered by authority and led a logical mind to pursue its inquiries into difficult and obscure paths which might intimidate the more conventionally trained Towards 1888 Barlow came into contact with Prof H E Armstrong, from whom he received much encouragement and help, he also met Mr (now Sir) H A Miers and the writer and acquired from them most of his knowledge of formal crystallography He then spent some time with his family in Germany and made the acquaintance of Paul Groth, the crystallographer, occupying himself with the geometry of crystal structure, on returning to England he devoted himself to crystallographic work of a theoretical kind until his death at Stanmore on February 28, 1934

In summarising the work of an unconventional genius, it is not easy to proceed chronologically, Barlow did not attack problems in the order which they would naturally take in a textbook or in the present notice His work on the homogeneous partitioning of space may therefore be first reviewed

For a century past the view has prevailed that crystal structure consists in the similar repetition throughout space of identical units without regard to their shape or constitution Continuing earlier work by Bravais and others, Sohncke in 1879 introduced the idea of a regular point system as one in which the pencils of lines drawn from each point of the system to all the remainder are congruent with each other, the regular point-systems if classified according to the position and nature of their axes of symmetry (whether screw axes or axes of rotation) are 65 in number The 65 Sohncke systems, if built up of mathematical points, do not account for all the types of symmetry represented by the 32 crystal systems, it will be seen at once that the structure of hemimorphous crystals, in which a polar axis is present, cannot be described by a Sohncke system without some further assumption, such as polarity of the points or of the component atoms or molecules

The development of Sohncke's work needed to provide a complete geometrical theory of crystal structure was undertaken independently by Schönflies, Fedorow and Barlow all three solved the problem but by different methods and the line of attack adopted by Barlow may be now briefly indicated Each Sohncke system is characterised by certain coincidence movements, these being translations and rotations about an axis of symmetry, which leave its appearance unchanged, further, a number of the Sohncke systems are enantiomorphous, that is, not identical with their mirror images Barlow duplicated the enantiomorphous Sohncke systems by intercalating the mirror image in such a way that the coincidence movements of the two component point systems coincide, he worked out the geometrical methods, three in number, by which this duplication can be effected The 65 Sohncke systems thus became increased by another 165 to a total of 230, these are known as the 230 space groups and represent all the types of symmetry possible in crystal structures Each of the 32 crystal systems corresponds to one or more of these space groups With the proof that the space groups number 230, the geometrical theory of crystal structure becomes practically complete and the foundation is provided upon which any mechanical or physical theory of crystal structure must be erected Whilst the methods used by Barlow in carrying out this difficult and laborious piece of work are perhaps less elegant than those of Schönflies, they offer certain advantages by the lucidity with which they reveal the geometrical properties of the space-groups

Although Barlow published his work on the space groups in 1894, he had for long been engaged on the second part of the problem of crystal structure, that of the mechanical nature of the structure (NATURE, 29, 186, 205, 1883) He assumed that equilibrium requires that the atoms composing a crystal structure shall be arranged in closest packing and showed that two closest packed assemblages of equal spheres exist, one of these has cubic symmetry and is known as the face centred cubic packing whilst the other has full hexagonal symmetry Modern X ray analysis has now shown that most of the metals assume these structures, although some are in the looser body centred cubic packing The recognition that equilibrium demands that similar spherical atoms shall arrange themselves in one or other of the two closest packed assemblages, and that these occur in many of the metals, was the first definite success achieved in associating specific geometrical structures with specific crystalline substances, the importance of this result has been but too little appreciated

In his paper of 1883 in NATURE, Barlow discussed the crystal structure of biatomic compounds, and suggested as one possibility for sodium chloride a body centred cubic arrangement in which one kind of atom lies at the cube centres and the other at the corners, this structure has now been shown by X-ray analysis to belong to cæsium chloride but not to sodium chloride It is of interest to recall Sohncke's objection to this structure, he says (NATURE, 29, 383, 1884) "Thus eight atoms of Na stand in exactly identical manner around an atom of Cl (and also eight atoms of Cl around an atom of Na) The atom of Cl seems consequently to be in equally close connection with eight atoms of Na, it has exactly the same relation to those eight atoms It appears therefore as octovalent, certainly not as univalent, for it would be entirely arbitrary to suppose any two neighbouring atoms of NaCl in an especially close connection and to take this couple for the chemical molecule of NaCl By this example we see that from Mr Barlow's point of view both the notion of chemical valency and of chemical molecule completely lose their present import for the crystallised state" This, which was an objection fifty years ago, is now regarded as one of the merits of the accepted cæsium chloride structure, Barlow's reply to Sohncke (NATURE, 29, 404, 1884) states the modern view

Barlow expanded his earlier notions on crystal structure in a long paper entitled "A Mechanical Cause of Homogeneity of Structure and Symmetry" published in the *Proceedings of the Royal Dublin Society* for 1897 under the auspices of Prof G F Fitzgerald, this provides a great deal of information as to possible symmetrical structures Later, with the present writer, the conception was introduced that the atoms, supposed spherical, occupy volumes in the crystal structure proportional to their valency and, in papers published between 1906 and 1910, a large mass of experimental crystallographic data was reviewed It was found possible, with the aid of the closest-packing valency volume hypothesis, to correlate many morphotropic relations with chemical constitution and crystal structure

In 1912, however, the first observations on the diffraction of X rays by crystalline substances were made and opened the way to direct methods for determining structure, these, brilliantly handled by W H and W L Bragg and their followers, have furnished precise experimental data as to the arrangement of the atomic centres in a vast variety of solid structures It is now clear that Barlow's mechanical theory was stated in too simple a form to be applicable to any but the most simple cases, it seems now impossible that crystal structures are, in general, close-packed assemblages of spherical atoms In this connexion it is significant to note that if the cubic closest-packed assemblage of equal spheres is symmetrically partitioned into tetrahedral groups of four spheres, the centres of these tetrahedral groups form the well known Bragg structure for diamond, the diamond may thus be pictured as a close packed assemblage of atoms which have the symmetry elements of the regular tetrahedron Although X-ray analysis has increased our knowledge of crystal structure in an astounding way and has proved a most powerful tool, it has not led to a mechanical theory of crystal structure, it reveals the atomic arrangement but offers no reason why the component atoms seem to be closely packed in some crystalline structures and only loosely in others The required mechanical theory of crystal structure may be found in some kind of generalisation of Barlow's conception of equilibrium conditions

Barlow was elected into the Royal Society in 1908 and was president of the Mineralogical Society from 1915 until 1918 He was a man of simple tastes, very happy in his family life and happy in his friends, he was an expert cabinet maker, and this was helpful in the construction of complex models of crystal structures It was never easy to follow his train of thought because he invented his own ways for attaining results, thus, he rarely used the classical methods of spherical trigonometry in crystallographic calculations, but devised special ones of his own for each case which arose Whilst Barlow's friends will remember his single-mindedness and his kindliness of heart, he will always rank among the master builders of the geometrical theory of crystal structure

W J POPE

DR FRED IBBOTSON

THE death of Dr Fred Ibbotson on February 5, at the age of sixty six years, brings a sense of personal loss to many metallurgists, especially to those connected with the steel industry of Great Britain As senior lecturer in the Metallurgical Department of the University of Sheffield until his retirement last year, he was responsible for training many students in metallurgical analysis, and his skill both as an analyst and as a teacher was largely responsible for the high standard of accuracy now reached in works manufacturing the higher classes of steels His course of lectures on the theory of analysis was an admirable introduction to the advanced chemistry of the less common metals and their salts

Dr Ibbotson made many improvements in analytical methods, and the textbooks in which he collaborated—"Steel Works Analysis" (with the late Prof Arnold), "Analysis of Steel Works Materials' (with H Brearley), and "Analysis of Non Ferrous Alloys" (with L Aitchison) are widely used A fellow townsman of Sorby, he was an early worker in metallography and translated the well known work of Goerens, whilst the papers of Prof Arnold in the *Journal of the Iron and Steel Institute* were often illustrated by his exquisite drawings of micro structures

Dr Ibbotson was born in Sheffield, but studied at the Royal College of Science in Dublin, of which he became an associate in 1887 He was a B Sc of London and a D Met of Sheffield Of striking appearance, great charm of manner and high character, he was greatly beloved by his students, only a very retiring disposition, which led him to shun meetings, prevented his reputation from reaching a wider circle C H D

WE regret to announce the following deaths

Mr Carsten E Borchgrevink, the Norwegian antarctic explorer, leader of the first expedition to winter in Antarctica, aged sixty nine years

Sir Richard Garton, G B E, governing director of the firm of Garton Sons and Co, brewing sugar manufacturers one of the founders of the British Empire Cancer Campaign, on April 22, aged seventy six years

Mr Richard Llewellyn Jones Llewellyn, an authority on rheumatism and its allied conditions, on April 19

Sir Max Muspratt, Bt, president of the Association of British Chemical Manufacturers in 1924, a leading figure in the heavy chemical industry, on April 20, aged sixty two years

Prof John M Poor, professor of astronomy at Dartmouth College, Hanover U S A who did much work on the orbits of comets, asteroids and double stars, aged sixty three years

News and Views

James Mansergh, F R S (1834–1905)

ON April 29 the centenary occurs of the birth of James Mansergh, the eminent hydraulic engineer, who, both at home and abroad, was well known for his schemes for water supply and sewage disposal His most famous work was that by which Birmingham was supplied with water from the Elan and Claerwen Reservoirs in Wales, 73½ miles away a work which was opened by King Edward VII on July 21, 1904 Mansergh was born in Lancaster After attending the local schools, he was at Queenwood College, Hampshire, for a short time, where Tyndall and Edward Frankland were among his teachers At the age of fifteen years he was articled to a firm of civil engineers in Lancaster and afterwards gained experience on railway construction in England, Wales and Brazil In 1866 he became a consulting engineer in Westminster, and from that time onwards specialised in water supply and sewage schemes It is said that he appeared more than six hundred times before Parliamentary committees, acted for three hundred and sixty municipalities or local authorities, wrote more than two hundred and fifty reports and gave evidence at about three hundred public inquiries Among the important schemes he carried out abroad were those connected with the water supply of Toronto and the sewage disposal of Colombo and Melbourne Entering the Institution of Civil Engineers in 1859 as an associate member, he became a vice president in 1895 and president in 1900 The following year his services as a hydraulic engineer were recognised by his election as a fellow of the Royal Society He died at Hampstead on June 15, 1905

Presentation to Prof Karl Pearson, F R S

WHEN the impending retirement of Prof Karl Pearson from the Galton chair of eugenics and from the directorship of the Biometric Laboratory at University College London was announced last year, it was felt desirable that steps should be taken to commemorate the pre eminent services which he had rendered to University College, to the University of London and to science, during nearly half a century An influential committee under the chairmanship of Prof L N G Filon, Vice Chancellor of the University of London, therefore decided to raise a commemoration fund for the purpose, Dr Ethel Elderton acted as honorary secretary and Dr David Heron as honorary treasurer of the fund As a result of the appeal then made, subscriptions amounting to more than £600 were received and at a dinner in Prof Pearson's honour at University College on April 23, under the chairmanship of Prof Filon, attended by some hundred subscribers, there were presented to Prof Pearson a bronze portrait plaque, a book containing the signatures of all the subscribers and a cheque for the balance of the fund,

£440, a Brunsviga calculating machine for his personal use had previously been presented to him The bronze plaque, of which a copy is to be presented to University College, and a small reproduction to each subscriber, bears the following inscription 'Presented to Professor Karl Pearson, M A, LL D F.R S, by students, colleagues and friends on his retirement after having been a Professor of University College, London, for forty nine years, in grateful commemoration of his research, teaching and inspiration" The balance of the fund is to be devoted to the completion or publication of such work of Prof Pearson or his pupils as he may select or to the advancement in any other way of the branches of science with which his name will always be associated Prof Filon, in making the presentation, paid eloquent tribute to Prof Pearson's distinction in so many fields, and was followed by Mr G Udny Yule, who gave very interesting personal reminiscences of work and holidays with K P

Joseph Priestley

THE recent issue of *Isis* (pp 81–97) contains an important paper by Mr W Cameron Walker on The Beginnings of the Scientific Career of Joseph Priestley", disposing of the incorrect views expressed by Priestley's biographers, such as, that his History of Electricity" was suggested by Franklin and that it led to his election as F.R S, that this distinction was the result of his electrical experiments, and so on The Canton Papers and certain letters—some facsimiles are given—in the Royal Society's library show that the writing of the 'History" was Priestley's own idea that he was elected F R S prior, not only to its publication, but also to his experiments, and that his friends secured his election with the view of increasing the sale of his book Priestley's own account, written long after these events, ascribed his election to his original experiments But the author is probably correct in hinting at a lapse of memory, since there is other evidence of this failing The most interesting document here is Seddon's letter of December 18, 1765, introducing Priestley to Price and suggesting in a postscript his introduction to Franklin As a result Priestley met Franklin and Canton, was elected F R S, was led to experiment in electricity, thence to the study of the conductivity of mephitic air', and thence to his classic chemical researches on 'airs' and to the discovery of oxygen—to the birth of modern chemistry Few postscripts' have had such historic consequences

Trevithick Memorials

A MEMORIAL to Richard Trevithick, the great engineer and inventor, was unveiled at Merthyr Tydfil on Thursday, April 19, by Mr David E Roberts, to mark in a fitting manner the historic journey of the first rail locomotive on February 21, 1804 The memorial is situated at Pontmorlais, close to what was then the entrance gate to Penydarren Ironworks, where Trevithick built the locomotive It ran down to the basin on the Glamorganshire Canal at Abercynon 9¾ miles distant, but the damage to the cast iron rails, which were of course only suited for horse traction, was such that the trials were not followed up The memorial itself is built of stone sleepers taken from the track, and incorporates also some of the old rails Its erection is the outcome of local effort backed by help from the Trevithick Centenary Commemoration in London The event was made a civic occasion, and a concourse of upwards of 3,000 spectators assembled for the ceremony The unveiling was followed by an address from Mr Roberts on the work, especially that in South Wales of Trevithick

THE second of the memorial tablets erected as a result of the commemoration last year of the centenary of the death of Trevithick, was unveiled at University College, London, on April 23 by the Hon Oliver Stanley, M P, Minister of Transport The tablet has been placed on the Gower Street side of the College to mark the site of the track laid down in 1808 over which Trevithick's locomotive *Catch me who can* ran This was the first rail locomotive to draw passengers, and the exact site of the experiment has only been determined after long inquiry The tablet, which bears a medallion of the inventor a representation of his engine and a suitable inscription, is of bronze, it is a bold and striking memorial and one which effectively attracts the attention of the passers by Prior to the unveiling, a meeting took place in the College which was presided over by Sir Murdoch Macdonald, M P, the chairman of the commemoration committee When asking Major Stanley to unveil the memorial, and the Provost of the College, Dr Allen Mawer, to accept the custody of it, Sir Murdoch said that often our great benefactors have reaped but posthumous honours and so it was with Trevithick, for although he died in 1833 it was not until fifty years later that his memory was honoured by the erection of a window in Westminster Abbey Methods of transport have developed greatly since Trevithick's time, but all our steam locomotives, great and small work on the principle first effectively applied by him

Cosmic Rays

PROF P M S BLACKETT delivered the Friday evening discourse on April 20 at the Royal Institution, taking as his subject Cosmic Rays" This fascinating subject started more than thirty years ago with the discovery that clean dry air at sea level is a slight conductor of electricity, it has now grown into one of the important branches of physics, and it perhaps may also be considered as an important branch of astronomy For whatever the final explanation of the origin of the rays is found to be, it is probable that their origin is of great astronomical significance The instruments with which the rays have been investigated have been the ionisation chamber, the counter and the cloud chamber, and experiments have been carried out with such apparatus all over the world and at very great heights above the ground and far below the surface The cosmic radiation is a part, really, of geophysics, to be studied not only in the laboratory but also everywhere that is attainable It appears from all these results that the earth is being bombarded by streams of positrons and electrons of very great energy These appear to come continually from outside our galactic system, but from where, or how they are produced, no one knows The study of the passage of these rays through the atmosphere has led to the discovery of exciting new phenomena The positron, first detected by Anderson in a cloud photograph, is now known to be one of the main constituents of the rays, and this new member of the group of fundamental particles has very great theoretical interest, since its experimental detection has shown the validity of Dirac's theory of holes' Very great interest is attached to the behaviour of the very fast cosmic ray particles while passing through matter The curious and striking phenomenon of the showers' still awaits explanation It is clear that one is here in a region of physics where quite new types of phenomena occur

Humour and Humanism in Chemistry

UNDER this title, Prof John Read, of the University of St Andrews, gave an address to the Alchemists Club of the University of Glasgow on February 28 One of the chief defects in the average science course or textbook he said, is the neglect of the human element He deprecated this omission, which he holds responsible for many of the misconceptions of men of science by their colleagues of arts and letters, who, from attending a limited number of strictly formal and impersonal lectures on science have often deduced that the man of science is of necessity cold, formal and aloof, narrow in outlook, insensible to the finer human emotions, incapable of expressing himself in the common tongue, devoid of humour and humanism, and a stranger to the humanities' In the course of a picturesque survey of selected aspects of historical chemistry, Prof Read claimed that the study of chemistry, if approached befittingly, may reasonably take rank beside the so called humanities', as a broadly educative, cultural, and humanising influence He re-defined humour in various terms as the golden thread running through the whole history of chemistry the real philosopher's stone—the universal catalyst The present generation of chemists, he remarked, are inclined to take themselves too seriously, like Liebig, Wöhler, and their more remote alchemical forebears, they should include a large pinch of humour and humanism in their curricula The narrowness of outlook which is becoming increasingly associated with the ultra specialistic trend of contemporary chemical research can be combated most effectively by the cultivation of an interest in the broader humanistic aspects of chemistry Those chemists who aspire to become leaders in the future should cultivate a discerning and sympathetic acquaintance with the past During the ensuing discussion, in reply to Prof T S Patterson, the speaker threw some new light upon the possible origin and interpretation of the enigmatical seventeenth century illustrations appearing in the *Mutus Liber*

74-in Telescope for the University of Toronto

THE issues of *Engineering* for March 9 and 30 and April 20 contain a fully illustrated description of the 74 in reflecting telescope now being completed by Messrs Sir Howard Grubb, Parsons and Co, at Newcastle for the David Dunlap observatory of the University of Toronto An account of the instrument was published in NATURE of October 14 1933 The observatory, which is being given as a memorial to the late David A Dunlap, of Toronto, by his widow and son is being erected on Richmond Hill, 800 ft above sea level a few miles north of Toronto The circular steel building and the 61 ft dome for housing the telescope were made by Messrs The Cleveland Bridge and Engineering Co, Ltd at Darlington, and these together with the main parts of the telescope were sent to Canada last year The polishing of the mirror is now in hand The telescope the largest in the British Empire and the second largest in the world, weighs about 50 tons, of which the moving parts account for about 35 tons The polar axis is 22 ft long and the declination axis 13 ft long, the driving wheel on the former having a pitch diameter of 8 ft with 960 teeth of 8 mm pitch The whole gives details of the driving and controlling mechanisms The disc for the mirror, of special Pyrex glass, was made by the Corning Glass Works, New York and when received at Newcastle weighed 2 tons 6 cwt For grinding and polishing the mirror a special machine has been made which allows the mirror to be tilted for testing purposes without being removed from the machine The telescope, it may be added may be used either as a Cassegrain or a Newtonian for which two mirrors 19 in and 20 in in diameter respectively are provided

THE David Dunlap Memorial telescope is illustrated in the issue of the *Sphere* dated April 21, which also includes photographs of the new 36 in Yapp reflector at the Royal Observatory, Greenwich Accompanying these illustrations is an article entitled Studying the Sun in Calcium Light' and several lunar photographs taken with the 100 in reflector at Mount Wilson, California

Scientific Publication and Bibliography

AN ambitious plan for scientific bibliography and publications is described in a memorandum issued by Science Service, Washington The plan is designed to eliminate some of the defects in our present system, such as the difficulty of publishing research results promptly or completely owing to the financial burden, and the inadequacy of much bibliographic work owing to lack of access to original papers, etc It is proposed accordingly to centralise all scientific publication, abstracting and similar bibliographic services, and to substitute a photographic type of duplication for printed reproduction of scientific papers or abstracts Under this scheme a research report, for example, submitted and accepted for publication, would be reproduced from the standard typescript form by some suitable method other than printing, and full copies of the report or paper would only be supplied to order. The author would, however, also provide a summary abstract, say, two hundred words in length, which after editing, if required, would be reproduced by the most suitable means and the abstract would be included in a weekly or monthly journal issued to all scientific workers desiring information in that particular field.

This scheme does not discuss the fundamental difficulty of overlapping, but obviously presupposes that one abstract could serve the needs of several related branches of science or industry. It also proposes to deal with the difficulty of indexing scientific literature by assembling all the necessary subject cards for each published article or report and using an adequate numerical classification together with mechanical finding and sorting devices, thus affording a comprehensive basis for bibliographic work. The scheme visualises a public utility association for the United States of America which could afterwards be developed on international lines. Despite the inherent difficulties in the project, and the fact that the international aspects are among the most important and difficult in the problem of dealing efficiently with scientific literature, it should not be lightly dismissed. Bold treatment on such novel lines may possibly lead to a rational solution of a problem which has so often been attacked half-heartedly.

Bureau of American Ethnology, 1931

In the forty-eighth annual report of the Bureau of American Ethnology for the year ending June 30, 1931, Mr. M. W. Stirling, chief of the Bureau, in making his usual report on the activities of his staff in the period under review, directs attention to archæological investigations carried out by him in Florida. Among the sites examined on the west coast was a large sand burial mound on Blue Hill Island, south of Key Marco, which was found to be of early post-Columbian Calusa origin. A number of structural features unusual in Floridan sand mounds was disclosed. Among them was a clay floor, six feet above the bottom of the mound, which gave evidence of having been the base of a temple structure. It was surrounded by post holes, in some of which the decayed remains of the wooden uprights were still in place. The ‘accompanying paper” of the report, which as usual takes up the greater part of the volume, does not on this occasion deal with researches in American ethnology carried out by members of the staff, but is a useful general index of the contents of the annual reports of the Bureau from their inception to date. It has been compiled by Dr. Biren Bonnerjea. Originally intended by Dr. Bonnerjea for his own use, the index has been adopted officially and published by the Bureau. As the early volumes cover the period in the 'eighties of the final resistance of the Indians to white control in the south-western States, they record much valuable material relating to the final stage of independent culture which the index will assist in preserving from oblivion.

Modern Street Lighting

The characteristic and peculiar colours of the discharge lamps used for street lighting have attracted much interest to this important public service. With the development and research departments of great companies behind it, this branch of lighting has made rapid progress. In a paper read to the Royal Society of Arts by J. M. Waldram on January 17, it was pointed out that the use of these lamps has led to material improvements in our knowledge, leading to a new technique. One of the immediate problems of street lighting is connected with the question of who is to pay for it. It is an anomaly that a national trunk road should be built, drained and maintained at the national expense, and the lighting left to local authorities, each lighting its section according to its own ideas and naturally being sometimes very limited as to the cost. The requirements of the motorist are the most difficult to satisfy. He has when moving at high speed to see every obstruction in the road many feet in advance, whatever the condition of the road surface. Claims have been made that certain lights have more fog-penetrating power than others, but recent experiments throw doubt on this. Experience shows that from the safety point of view, when driving, the spectral colour of the light matters little. In general, recent progress has been made mainly in the direction of lowering the cost of production of the light and thus making more light available, and in distributing it over the road in such a way that it is more helpful to both pedestrians and motorists.

Short-Circuit Testing Station

When an electric generator is accidentally short-circuited, huge currents are developed and unless the circuit breakers' act promptly, serious damage may be done to the generator and there is a risk of fire. Until a few years ago, practical experience was the only guide to the rating of these circuit breakers. The enormous currents required for testing purposes, in most cases, made the testing costs prohibitive. Proposals were made for a co-operative or national testing plant, but nothing materialised. In 1929 a private company, Messrs. A. Reyrolle and Co., Ltd., of Hebburn-on-Tyne, laid down their own testing station, which has proved capable of testing the largest circuit breakers used in Great Britain. They have erected a miniature power station which has a capacity of 1·5 million kilovolt-amperes. Any short-circuit conditions which might possibly occur in practice can be produced in their testing room. The generators are driven by 5,500 volt motors connected with the public supply mains. Very large transformers are used to produce the heavy currents required. The observation gallery is built of reinforced concrete and has slits in the wall fronting the test bay, through which the behaviour of the apparatus under test can be safely observed. A system of traffic signal lights and alarm bells is installed outside the test bay to give warning when a test is about to be made and when all is clear. Short-circuit phenomena can be observed in time intervals as short as two millionths of a second Messrs Reyrolle's plant is one of the largest and best equipped short circuit testing stations in the world A scheme has now been initiated whereby full facilities are provided for utilising this testing plant for the benefit of the electrical industry A company has been formed which will operate independently and will be in a position to issue national test certificates

A Piano with no Wires

ACCORDING to a recent report by Science Service, pianos are now being constructed in Kalamazoo, Michigan, U S A , with no strings or wires To produce the tones, strips of steel not more than a few inches long are made to vibrate electrically The new instrument, called a clavier, uses a piano keyboard to operate the strips producing the notes, which are practically pure tones These tones, which are almost inaudible, are picked up by magnetic induction and passed through an audio frequency amplifier The capacity of the amplifier is about ten times that of the average radio amplifier having a capacity of 30 watts The player therefore has at his command a tone ranging from a mere whisper to one that would balance an orchestra The impact noise sometimes audible in a piano is filtered out, and thus the pure tone is produced The piano was invented by Prof Lloyd Loar after experiments extending over several years Through the use of earphones, the piano student can practise his lessons without disturbing anyone, the sound being heard only by himself The tone volume can be varied over a wide range simply by turning a dial The operating devices occupy very little space, the clavier consisting of little more than keyboards

Ipswich Museum

AN appeal on behalf of the Ipswich Museum has been issued by Mr J Reid Moir, its president The Museum is not well provided with exhibits illustrating the culture of the bronze age , but it now has the opportunity of acquiring an exceptional collection of bronze implements, many of which were found in Suffolk, at a cost of £100 The collection is at present on view in the Museum Mr Reid Moir, in issuing his appeal, does not confine himself to this immediate object , he takes a long view of the situation Availing himself of the occasion, he suggests the institution of a body of Friends of the Museum" who might collaborate in its work in various ways, and might, by subscription, provide a fund for use in emergencies which the provision from municipal funds could not meet for various reasons The case for the local museum as a centre of regional scientific and historical studies is ably stated in the appeal and needs no further elaboration here On the question of general principle, however, it may be pointed out that any proposal such as that made by Mr Reid Moir, which helps to broaden interest among the local public in the function of its museum, deserves every encouragement Without desiring to relieve the municipality, as the local education authority, from any responsibility that may be imposed upon it for the maintenance of the general intellectual level of its area, it must be admitted that occasions frequently arise in connexion with the work of a museum in which voluntary effort financial or other, is salutary and expedient, or even necessary, to supplement the official obligation of the municipality

Grassland and Grazing Research

Two new bulletins in the Herbage Publication Series have been issued by the Imperial Bureau of Plant Genetics at Aberystwyth The first, entitled Grazing"(Bull No 10 1s 6d), consists of a collection of papers read at the British Association meeting at Leicester in 1933, each of which approaches the subject from a different aspect The grazier's problems are put forward from a practical man's point of view, while the effect of the stock on the sward is considered in the light of experimental evidence The Bureau has for some months been collecting information regarding the technique employed in pasture and grassland research in Great Britain and certain dominions, and the other bulletin ('Technique employed in Grassland Research in New Zealand , Bull No 11 3s) is the first publication on the subject Questions of strain testing and building in grasses, clovers or lucerne, the breeding methods employed and the necessary corollary—the certification of herbage seeds—form the subject of several of the papers The measurement of pasture production is considered in detail A modification of the technique formerly described as 'alternate mowing and grazing' is put forward, while the lay out of the experiments, the stage at which cuttings should be made, and the technique of stock grazing trials are among other major points dealt with Reference is also made to two laboratory tests which have proved useful in conjunction with field work In the first place the prussic acid content has proved valuable as a means of distinguishing between different types of wild white clover, while screened ultraviolet light has been successfully employed in rye grass type determination

Russian Studies of Crop Plants

THE material collected by Dr Klinkowski on the ecological distribution of lucerne types has been translated and published in an abridged form as Bulletin No 12 in the Herbage Publication Series of the Imperial Bureau of Plant Genetics ("Lucerne Its Ecological Position and Distribution in the World ' Aberystwyth I B P G , Agricultural Buildings 3s 6d) Lucerne is the oldest forage plant known and originated from a number of regions of a steppe' character The routes along which the plant migrated are traced, and the history of its development and the importance of the crop at the present time described for 45 different countries The geographical distribution of the types of cultivated lucerne in Europe, Asia and North Africa is also dealt with A further publication, "Plant Breeding in the Soviet Union", has been issued jointly by the Cambridge and Aberystwyth Sections of the Imperial Bureau of Plant Genetics (3s 6d)

White Pelicans of Western America

WHERE formerly there were more than seventy nesting colonies of white pelicans in western Canada and the United States, there are now but seven large colonies Of these, five are in Government protected areas, a fortunate circumstance, since although there still exist 20,000–25,000 of these birds in the United States, their continued existence is not so secure as the numbers might suggest. The danger which most threatens the species according to Ben H Thompson (Science Service, Washington, D C), is the draining of lakes where the nesting islands exist, but there has also to be taken into account the retaliation upon nests and eggs by fishermen who object to the pelicans destruction of fishes, notwithstanding that in most places the birds have been found to feed mainly upon fishes not good for sport or food A third line of control was practised for some time in Yellowstone Lake, on account of the part taken by pelicans as carriers of a trout parasite, but that policy has been given up, and the Yellowstone Park birds are now fully protected

Museums Association

THE report of the Council for 1932–33 makes very satisfactory reading The membership rose to 801, and is now really representative of museum interests throughout Great Britain. Income for the year at £2,785, was a record, the subscriptions of members exceeding by £268 those of the preceding year, and the net credit balance for the year was £496 The work of the Association has followed the lines of recent years Co operation with the Carnegie United Kingdom Trustees in the allocation of museum grants has been continued, and now all applications for grants must be made in the first place to the Association A successful training course for museum curators was held at Manchester, the annual conference of 1932 at Birmingham, and there is the great venture of an Empire survey of museums which began in 1931 (*Museums J* , 33, 206 , 1933) The same number of the *Journal* contains an account of the very successful conference of 1933 at Norwich

Solar Physics Observatory, Cambridge

THE annual report of the Director of the Solar Physics Observatory at Cambridge shows that a satisfactory state of progress obtains at that institution (University of Cambridge Solar Physics Observatory Twenty first Annual Report of the Director of the Solar Physics Observatory to the Solar Physics Committee, 1932 August 1—1933 July 31 Pp 3) The 3 ft reflector is at last being put to regular use, and as a spectrograph will be obtained for it in the near future, we may look forward to a notable addition to the somewhat slender amount of stellar spectroscopy carried out in Great Britain The Solar Physics Observatory has recently acquired additional solar apparatus in the form of a fine train of prisms by Hilger There is now a good collection of spectrographs at the Observatory As in past years, a number of physicists from the Cavendish Laboratory have gone out on the Madingley Road and worked at the Observatory

Bibliography of Cossar Ewart's Works

PROF J H ASHWORTH and Dr F Fraser Darling have prepared a ' Bibliography of the Works of James Cossar Ewart ', who died on December 31 last (Supplement to Animal Breeding Abstracts vol 1 Edinburgh Oliver and Boyd Separate, 6d net) The list, which contains no less than 141 titles of papers and books by Cossar Ewart alone or in collaboration with others is a story of a long and active life of scientific investigation covering a wide range of work, from minute anatomy to animal breeding The last reference is to a letter on The Coat of Sheep ' in NATURE of March 19, 1927 , it is also of interest to note that nine of Cossar Ewart s papers to the Royal Society of Edinburgh are represented by title only, so that the abstracts published in NATURE are the only records of their subject matter

Academic Assistance Council

REFERENCE has been made in our columns from time to time to the work of the Academic Assistance Council, one of the functions of which is to assist men of science and letters who have been displaced during the political changes in Germany of the past year or so We understand that the Council has now compiled a list of such displaced scholars, with information as to whether they have succeeded in obtaining temporary or permanent posts The list is to be revised from time to time and sent to academic committees and appropriate institutions The Council, the address of which is c/o Royal Society, Burlington House, London, W 1, is prepared to give further information about the movements of those on its lists in reply to responsible inquiries

The Pasteur Institute of Southern India, Coonoor

THE annual report of the Director, Major K R K Iyengar, of this anti rabic Institute for the year 1932 has recently been issued Patients treated at the Institute numbered 566, with 4 deaths, a mortality rate of 0 7 per cent In addition, the anti rabic vaccine is now issued to 107 centres in the Madras Presidency and elsewhere, and at these 8,452 persons are reported to have received a complete course of treatment, among whom were 34 deaths, a mortality rate of 0 4 per cent Semple's carbolised sheep vaccine was used throughout the year, and 144,900 doses of this vaccine were issued , in addition to the human patients, 194 animals were also treated No record of research work appears in this report

The Apennine Tunnel

ON April 22 the King of Italy opened the new railway line joining Bologna and Florence Known as the 'Direttissima", this line is 21 miles shorter than the old line known as the 'Porretana" The total distance is 61 miles, of which 23 miles are underground Many bridges and viaducts have had to be constructed but the outstanding feature is the Apennine Tunnel, 11 miles 882 yards in length, which is the longest tunnel in the world with a double track The Simplon tunnel is slightly longer, but this consists of two parallel tunnels each with a single track The Apennine tunnel is a straight line for the whole length and, half way through, a station has been built with four lines for manœuvring purposes Electric traction is being used, the locomotives taking direct current at 3,000 volts The total cost of the line has been about £13,000,000, while the saving of time on the journey between Bologna and Florence is about one hour and a half

Rothamsted Experimental Station

OF the £30,000 required for the purchase of the land on which stands the Rothamsted Experimental Station, £26,700 has now been given or conditionally promised The sum of £3,300 remains to be raised before May 12 in order that the Station may claim the generous donation of £15,000 from Mr Robert McDougall and £5,000 from the Sir Halley Stewart Trust, which will complete the purchase fund Farmers and all interested in agriculture in its practical, technical or educational aspects are cordially invited to visit the Rothamsted and Woburn plots at any convenient time between the beginning of May and the end of October Mr H V Garner and Capt E H Gregory will be in charge of the demonstrations, and there is ample material at either of the farms to occupy a full day All communications and requests to visit the Stations should be addressed to the Secretary, Rothamsted Experimental Station, Harpenden

Announcements

SIR ARTHUR EVANS has been awarded the gold medal of the Society of Antiquaries for "his distinguished services to archæology" This is the first award to be made of the medal

BRIGADIER GENERAL SIR PERCY SYKES has been awarded the Gold Medal of the Royal Empire Society for his recently published book "A History of Exploration from the Earliest Times to the Present Day"

PROF C V BOYS will deliver the nineteenth Guthrie Lecture before the Physical Society on May 4 at 5 p.m The title of Prof Boys's lecture will be "My Recent Progress in Gas Calorimetry"

THE third Spiers' Memorial Lecture of the Faraday Society will be delivered at the Royal Institution on May 16 at 5 30 p m by Sir William Bragg, who will take as his subject "Molecule Planning"

AT an ordinary meeting of the Chemical Society to be held on May 3 at 8 p m, a discussion on "Unicellular Chemistry" will be opened by Dr J Vargas Eyre Those invited to take part in the discussion include Dr E F Armstrong, Dr W G Bennett, Prof J C Drummond, Dr H B Hutchinson and Miss M Stephenson

SIR CHARLES PEERS, chief inspector of ancient monuments in 1913–33, has been appointed by the Lords Commissioners of the Treasury to be a trustee of the London Museum

DR R MADWAR has been appointed director of Helwan Observatory, near Cairo, in succession to Mr P A Curry, who is the Deputy Director General of the Physical Department, Ministry of Public Works, Egypt

THE annual meeting of the Iron and Steel Institute will be held at the Institution of Civil Engineers, Great George Street, Westminster, S W 1, on May 31–June 1 The autumn meeting of the Institute will be held in Belgium and Luxembourg on September 10–14

W JUNK, 68 Sachsische Strasse, Berlin, W 15, has just issued Catalogue 85, "Periodica Iconographiæ Rara et Curiosa" dealing with books on science and natural history The first section includes sets of periodicals, mainly foreign Iconographiæ contains chiefly coloured plate books, including several botanical rarities The last section has books on all branches of natural science, both standard modern works and earlier works of historical interest

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —An assistant lecturer in geography in the University of Manchester—The Registrar (April 30) An assistant master to teach mathematics in the School of Art and Technology, Chelmsford—The Clerk to the Governors, School of Art and Technology, Chelmsford (April 30) A chief technical assistant in the Department of Economics, Edinburgh and East of Scotland College of Agriculture—The Secretary, 13, George Square, Edinburgh (May 4) An assistant master to teach practical drawing in the Walton Junior Day Technical School, Liverpool—The Director of Education, 14, Sir Thomas Street, Liverpool 1 (May 4) A lecturer in bacteriology and assistant bacteriologist in the Public Health Laboratory, University of Birmingham—The Secretary (May 10) A veterinary surgeon in the Public Health Department of the Corporation of London—The Town Clerk, Public Health Department, Guildhall, E C 2 (May 10) A principal of the Central Municipal Technical School, Liverpool—The Director of Education, 14, Sir Thomas Street, Liverpool 1 (May 14) A teacher of mechanical engineering in the Central Municipal Technical School, Liverpool—The Director of Education, 14, Sir Thomas Street, Liverpool 1 (May 14) A demonstrator in physiology in the University of Liverpool—The Professor of Physiology (May 14) A Ramsay Memorial professor of engineering at University College, London—The Academic Registrar, University of London, S W 7 (May 23) A University professor of pharmacology at University College, London—The Academic Registrar, University of London, S W 7 (May 25).

Letters to the Editor

Production of Positive Electrons by β-Particles

In a previous note[1] we described some experiments carried out with a weak source of radium placed inside an expansion chamber, and showed that the ordinary β radiation is accompanied by an emission of positrons It is quite impossible to ascribe the origin of these positive electrons to the internal conversion of γ rays or to any other known mechanism by which positively charged particles are created It seemed to us to be most plausible to assume that the appearance of these positively charged particles is closely connected with the phenomenon of β-disintegration However, more recent experiments have shown that the number of positrons depends to a large extent upon the nature of the walls surrounding the source examined

In a series of consecutive experiments with the same source of radium, the latter was alternately enclosed in either a lead or a carbon tube with different thicknesses of wall provided with different slits for the escape of the β rays With a carbon tube the number of positrons observed was two to three times greater than in the case of a lead tube This would lead to the conclusion that the emission of positrons is due, at least in part, to the bombardment of the walls by β rays

We verified this assumption in the following way The glass tube containing the active deposit, and surrounded by another tube of lead, was filled with pulverised carbon , in this case we observed a threefold increase in the yield of positive β rays (each time compared with the yield of ordinary β rays due to disintegration escaping through the given aperture)

Quite conclusive evidence was obtained by using a lead cylinder with walls 4 mm thick and internal diameter 6 mm A window 4 mm wide in the walls was closed by a carbon filter, 3 mm thick, for absorbing any positrons emitted by the active source, and for stopping all the ordinary β rays of energy less than *c* 1,000 ekv Under these conditions, the carbon filter emits very fast positrons (12 tracks with an energy between 200 ekv and 700 ekv , 7 tracks with an energy between 700 ekv and 1,200 ekv) their number constituting 5–10 per cent of the total amount of β rays which *penetrate* the filter

If we assume, on the basis of the present data on the absorption of β rays, that all the β rays of initial energy above *c* 1,000 ekv are able to penetrate the filter, and that these are the only rays which are effective, the results obtained must mean that, on the average, one positron corresponds to every 10 or 20 β particles and that the radius of the 'effective cross section' is of the order of 10^{-12} cm

The number of β particles which strike the filter, and are responsible for the appearance of positrons, may exceed the number of particles which emerge However, if we take into account the geometry of the experimental arrangement as well as the intensity of the source under examination, we shall be justified in concluding that the percentage yield of positrons is scarcely less than 2 per cent, the critical energy being taken as 1,020 ekv In this case the radius calculated for the effective cross section is not less than $0\ 5-1 \times 10^{-12}$ cm per atom, which exceeds the corresponding value for the γ rays of thorium C″ some ten times

Thus it is obvious that the above phenomenon has nothing in common with the mechanism considered by Furry and Carlson[2] We here encounter an entirely new relativistic effect which is outside the scope of the present theory

It may be added that the above results are in good agreement with previous observations made by one of us[3]

At the present moment it would be premature to decide whether the positrons are emitted by the radioactive substance itself The observed facts seem to indicate that the output of positrons is greater for the lighter elements Definite conclusions must be deferred until new experiments have been carried out, since the geometrical conditions up to the present could not be controlled sufficiently

Isomorphism and Chemical Constitution Constitution of Formic Acid and Formates

That formic acid differs from its higher homologues (acetic, propionic, etc) in many salient chemical characters is well known to chemists The break in the serial order as regards the absorption curves of the saturated monobasic fatty acids has been observed in the case of formic acid by V Henri, Hantzsch and Wright

The reducing character of formic acid, generally explained by the presence of an aldehydic group in the molecule, as distinguished from acetic acid and its homologues, the absence of a chloride and anhydride corresponding to acetyl chloride and acetic anhydride, the acid character of its nitride (HCN) differing from the indifferent nitrides of homologous acids, the strength of the acid twelve times stronger than acetic and propionic acids as shown by the affinity constants derived from electrical conductivity (Ostwald), have rightly induced Richter to differentiate it from acetic acid and its homologues Dr P B Sarkar, working in the inorganic department of my laboratory, has, in continuation of his work on chemical homology and isomorphism[1,2], recently arrived at the conclusion that these discrepancies are to be sought for in the difference in the constitution of the acid itself In other words, in the case of formic acid, the ionisable hydrogen is not the hydrogen atom of the hydroxyl group, as in the case of other fatty acids, but the hydrogen attached to the carbon atom

The classical synthesis of formates from CO and KOH is explained by Dr Sarkar on the modern electronic conception in the following way :

$$:C \equiv O: + K^{+} + \bar{O}H \longrightarrow K^{+} + \left[:C{=}O\right]^{-}$$

The hydroxyl ion co-ordinates with the group CO to which it imparts an univalent negative charge and thereby forms a complex anion (formate ion) The so-called bivalent carbon atom in this anion has really a lone pair' of electrons free Dr Sarkar has proved that the undissociated formic acid and its esters are not reducing although they contain the aldehydic group It is the formate ion that is reducing owing to the presence of a lone pair' of electrons in the carbon atom The undissociated acid, according to him, is of the constitution

In this form it is indistinguishable from the ordinary formula

as is evidenced by the Raman spectra On the basis of this hypothesis, Dr Sarkar deduces that the structure of the formate ion is almost identical with that of the nitrite ion

These two ions are isosteric and isoelectric and as such should exhibit isomorphic relations

Though barium formate crystallises anhydrous and barium nitrite with one molecule of water of crystallisation, Dr Sarkar has been able to prepare the mixed crystals of

1, barium (formate, nitrite) barium (nitrite formate), H_2O

2, Strontium formate with strontium nitrite

3, Zinc formate with zinc nitrite though the latter cannot be isolated in the free state

4 Cadmium formate with cadmium nitrite (miscibility small)

He has also prepared the double salts of the formulæ

Mg $(COOH)_2$, 2 hexamethylene tetramine, 10 H_2O
Mn $(COOH)_2$ 2 hexamethylene tetramine, 10 H_2O

perfectly isomorphous with the corresponding nitrites of magnesium and manganese prepared by Scagliarini[3] Further investigation regarding the double and triple formates and their comparison with the corresponding nitrites is in progress

To corroborate the above constitution of the formate ion, the examination of the Raman effect of barium formate in the solid state has been undertaken and is expected to throw additional light on the constitution

Detailed investigation will be published in the *Journal of the Indian Chemical Society*

Conductivity-Temperature Curves of Paraffin Wax

IT is usually supposed that the conductivity of dielectric materials increases continuously with increase in temperature The only recorded exception to this normal behaviour appears to be by Gemant[1], who found that the D C conductivity of a heavy cable oil decreased temporarily from − 40° to − 20° C I have recently observed a similar peculiar phenomenon, together with a hysteresis effect, in D C conductivity measurements over the temperature range from 0° to 50° C on a sample of paraffin wax (melting between 45° and 55° C) The results of a cycle of measurements under a continuously applied voltage gradient of 500 volts per cm are shown in Fig 1 Commencing at the point *A* the temperature was lowered to *B*, then raised at a rate of about 1° C in 5 minutes along the curve *BCD* and finally decreased at the same rate along *DFB* On regaining room temperature very slowly from *B* the conductivity had risen to *F*, and with temperature rise from this point followed the curve *FGD* On subsequent slow cooling to room temperature the conductivity attained the value *H*

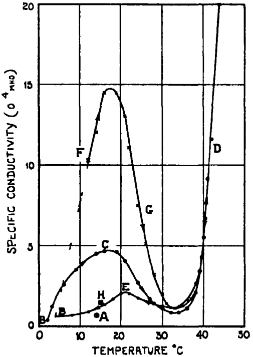

FIG 1

A discharge current, characteristic of dielectric absorption, lasting usually for from 1 to 2 minutes, was obtained on condenser short circuit immediately after a period of charge Measurements at 10 seconds after short circuit showed that the current magnitude at this instant passed through a maximum during temperature rise at 12° C and disappeared in the region of 55° C

A satisfactory explanation of the peculiar variations in structure responsible for the phenomena is not possible until further experiments have been carried out, but it is probably concerned with the presence in the wax, at temperatures below the 'solidifying' point, of a solid crystalline network among which is interspersed a liquid phase In consequence of adsorbed ions, the boundary surfaces of the two phases would have a greater conductivity than either phase, and where continuous, would form highly conducting bridges between the electrodes

Calcium Sulphate Hemihydrate

Much attention has been given to calcium sulphate hemihydrate since it was recognised as the active principle of plaster of Paris, but its characteristics as a crystal species have hitherto remained somewhat vague

Several workers have reported on the preparation of the pure substance in the wet way by various methods, but always in the form of excessively small crystals It has now been found possible to grow crystals of hemihydrate' of a thickness of 0 5–1 mm and length of 3–4 mm from solutions of calcium sulphate in hydrochloric, sulphuric, or nitric acids under the proper conditions as to dilution of the solvent and temperature These crystals belong to the trigonal system and consist of the hexagonal prism 1010 capped by an obtuse rhombohedron 0112 and terminated by small developments of the base 0001 The axes have lengths $a = 6\ 76$ A and $c = 6\ 24$ A, so that three molecules are comprised in the unit cell, the density of the crystal being not far below that of anhydrite Details will be published in a forthcoming paper

In its air-dry condition the crystal usually contains no more than 4 0–4 5 per cent of water, corresponding rather to 3 $CaSO_4\,H_2O$ than to 2 $CaSO_4\,H_2O$ The moisture content of hemihydrate' has, however, been shown by Linck and Jung and others working upon less well defined materials to be held in the same way as that of zeolites This is now confirmed with the trigonal crystals, which may be made to give up water to within a tenth per cent or less of complete dehydration without losing form or transparency, on exposure to moist air they then gradually regain the original degree of hydration On dead burning' they are converted into pseudomorphs consisting of ordinary anhydrite

Brought into contact with water, the crystals yield solutions supersaturated with respect to $CaSO_4\,2H_2O$, though the effect is not so striking as with plaster of Paris, in a short time bunches of dihydrate needles are seen growing out of favoured spots on the hexagonal prisms

It seems, then, that anhydrite is dimorphous, we have the orthorhombic, comparatively inert modification, and a trigonal one stable only up to 200° or thereabouts, which can take up water zeolitically The behaviour of this latter in contact with water is what causes plaster to set There may well be no essential difference between the 'soluble anhydrite' and the 'hemihydrate' accepted in the literature of calcium sulphate

The Value of e/m

Eddington[1] originally proposed the relation $hc/2\pi e^2 = 136$, and later[2] revised this to 137 Still later he proposed[3] a second relation, namely, the ratio of M, the mass of the proton, to m, the mass of the electron, is 1847 6[4] This second relation, combined with the value of the Faraday and Aston's mass of O^{16} leads[4] to $e/m = (1\ 77031 \pm 0\ 00014) \times 10^7$ E M units If, finally, one assumes the correctness of Bohr's formula for the Rydberg constant, there results[4], $h = (6\ 5490 \pm 0\ 0011) \times 10^{-27}$ erg sec, $e = (4\ 775855 \pm 0\ 000048) \times 10^{-10}$ E.S units

Bond[5] has very recently noted that the best experimental value of e/m, which he takes to be 1 759, is approximately 136/137 of Eddington's calculated value This new relationship is, however, closer than Bond states, since 136/137 (1 77031) = 1 7574, and the best experimental value is now actually 1 757 Thus Dunnington[6], from a new magnetic deflection method for free electrons, obtains 1 757 ± 0 0015 Gibbs and Williams[7], from the interval of corresponding $H^1\alpha$ and $H^2\alpha$ spectral lines obtain 1 757 ± 001 Kinsler and Houston[8], from the Zeeman effect of Cd and Zn lines, get 1 7570 ± 0 0010

The method used by Kretschmar[9] yields not e/m but $e/m\,(e^{4/3}/h)$[10] The observed value of this relation combined with Bohr's formula for the Rydberg constant leads to $e/m - 1\ 7564$ if the oil drop value of e (4 768) is assumed correct, and to $\sim 1\ 760$ if the value of e ($\sim 4\ 803$) deduced from grating values of X ray wave lengths is assumed correct These last two results are based on a recalculation of Kretschmar's observations by me, using improved auxiliary data Hence Kretschmar's work leads to a value of e/m entirely consistent with other recent work if one assumes the correctness of the oil-drop value of e 4 768 but not if the grating value, 4 803, is used

If the reader will pardon an additional intrusion into the popular domain of numerology[11], it may be noted that 4 803/4 768 = 137/136, to one part in 10^5

Reaction Mechanism of Oxidation-Reduction Processes

Certain considerations introduced by Franck and Haber[1], Haber and Willstätter[2] and Haber and Weiss[3] can be developed to give a simple mechanism for oxidation reduction processes in solution, which reproduces in all cases investigated the experimental observations, both qualitatively and quantitatively The relation sometimes observed[4] between reaction velocity and electrochemical potential can also be obtained, so that for the first time a comprehensive theoretical treatment becomes possible

The essential idea is the assumption of electron transfers mainly with ions (in some cases possibly the transfer of H), thus loss or gain of electrons always taking place one electron at a time, whereby radicals are often formed This principle also holds generally for oxidation of more than one step

For example, the mechanism of the oxidation of a bivalent positive (metal) ion (Me) by molecular oxygen would be

$$\mathrm{Me} \quad + \mathrm{O_2} \rightleftarrows \mathrm{Me} \quad + \mathrm{O_2'},\ \mathrm{O_2'} + \mathrm{H} \rightleftarrows \mathrm{HO_2}$$
$$(2\mathrm{HO_2} \rightleftarrows \mathrm{O_2} + \mathrm{H_2O})^3 \qquad (1)$$

$$\mathrm{Me} \quad + \mathrm{HO_2} \rightarrow \mathrm{Me} \quad + \mathrm{HO_2'},\ \mathrm{HO_2} + \mathrm{H} \rightleftarrows \mathrm{H_2O_2} \qquad (2)$$

$$\mathrm{Me} \quad + \mathrm{H_2O_2} \rightarrow \mathrm{Me} \quad + \mathrm{OH'} + \mathrm{OH} \qquad (3)$$

$$\mathrm{Me} \quad + \mathrm{OH} \rightarrow \mathrm{Me} \quad + \mathrm{OH} \qquad (4)$$

HO_2 and OH are the radicals thus produced The amount of hydrogen peroxide appearing as a reaction product is determined essentially by the speed of its further interaction by reaction (3) The autoxidation of certain organic compounds (hydroquinones leuco dyes, SH-compounds, etc), some of which are of biological interest[5], seems to proceed in a very similar manner

Without a metal catalyst, many of these substances are oxidised appreciably only in more or less alkaline media[6], in which the presence of double or at least singly charged anions (R″ or RH) has to be assumed In such cases we need only consider reactions (1) and (2) (H_2O_2 being formed as reaction product) the anion of the organic compound being substituted for Me The formation of the end product then results from the interaction of two radicals

$$2\mathrm{R} \rightleftarrows \mathrm{R''} + \mathrm{R} \text{ or } 2\mathrm{RH} \rightleftarrows \mathrm{RH_2} + \mathrm{R}$$

In seeking a relation between reaction velocity and electromotive force, it is first necessary in all these cases to determine whether reaction (1) is to be treated as an equilibrium practically always existent If this is so, we get the experimentally observed relation[7]

$$E_t = A_1 + K_1 \log t$$

holding (as a first approximation) during the course of the reaction, E_t being the E M F measured at time t, A_1 and K_1 being independent of E_t and t

In comparing the rates of oxidation of different substances, a relation has been established experimentally in certain cases[8] between the times (t_p) for a given percentage change and the normal potentials (E_0) of the oxidised substances This relation is of the form

$$\log t_p = A_2 + K_2 E_0,$$

A_2 and K_2 being independent of t_p and E_0

This relation can also be obtained theoretically if we make the plausible assumption that, for the series of substances for which the relation holds, the velocity coefficients of the electron transfer reaction (2) are all about equal

In more or less acid solutions, many of the above mentioned organic compounds are oxidised only in the presence of metal ions[9] The oxygen then attacks the metal ion directly (reaction 1) producing HO_2' and Me , one of which can then react further as the actual oxidising agent In the case studied by La Mer and Temple[10], the higher valent metal ion (Mn) is evidently the oxidising agent, and thus the relation they obtained between rate and potential can easily be deduced

There are further oxidation reduction processes of the type $R'' + Q \rightarrow R + Q''$ The oxidation of a given R″ by different Q and vice versa has been studied[11] From the mechanism

$$\mathrm{R''} + \mathrm{Q} \rightleftarrows \mathrm{R'} + \mathrm{Q'} \qquad (5)$$
$$\mathrm{R'} + \mathrm{Q'} \rightarrow \mathrm{R} + \mathrm{Q''} \qquad (6)$$

a bimolecular velocity coefficient results, in agreement with experiment[11] If the velocity coefficients for two different oxidising agents Q_a and Q_b, having normal potentials E_a^0 and E_b^0 are k_a and k_b the observed relation

$$\log \frac{k_a}{k_b} = \text{const } (E_a^0 - E_b^0)$$

follows again on the assumption of roughly equal velocity coefficients for reaction (6) in both cases

A full discussion will be published shortly

I wish to thank Sir William Pope for his kind assistance in many respects and Prof F G Donnan for his interest in this work

A New Guinea Fish Poison

SOME time ago Dr Hoaslip forwarded to me from Papua a sample of the root of a vine which he stated was used by the natives for two purposes, one, stunning fish from which the root receives its local name of New Guinea Dynamite, the other purpose is suicide

For a time I searched for active poisonous principles in the material, but finally reached the conclusion that the substance was a rotenone containing root its toxicity towards fish is thus accounted for, but its poisonous action on mammals becomes doubtful The root gives a strong colour test in the modified Durham reaction[1] and assays[2] of samples show a rotenone content of from four to five per cent Rotenone extracted from a parcel of the root by carbon tetrachloride, after recrystallisation from amyl acetate had $[\alpha]_D^{21\ 5}$ − 221 9 in benzene (*c*, 5 582) and had m p 164° which was not depressed when admixed with an authentic sample of rotenone.

Dr Wood, of this University, from an examination of the leaves, flower and fruit was of opinion that the plant was a *Derris*, a view which was confirmed by Mr White, the Government botanist of

Queensland A specific determination, however, was not possible on account of the quality of the material, and will have to await the arrival of further specimens this season

The native name for the root varies with locality, but it is known as *tua* or *tuva* on Dobu and Fergusson Islands I am informed that whilst *tuva* is used in some places in the Pacific specifically to denote *Derris elliptica*, in other localities it is used as a collective term for fish poisons in general

Reference is made to the New Guinea *tuva* in general literature[3], and also to the supposedly poisonous properties of the local *Derris* root but in the latter connexion I am inclined to think that the psychical effect of nauseating draughts on the natives cannot be overlooked

Polyspermy and the Endosperm

In preparing an account of the life history of *Acacia Baileyana* I have found strong evidence of polyspermy in connexion with endosperm formation The polar nuclei unfused before fertilisation have one large nucleolus each The sperm which on first contact with the polar nuclei has 13 chromosomes present[1] (presumably telophase) (Fig 1*a*) proceeds to the resting condition, with a small nucleolus (Fig 1*b*) In normal cases this group of two large and one small nucleoli is the most prominent feature of the centre of the sac at this stage Fusion is first between the sperm and one polar nucleus (Fig 1*c*) the product then fusing with the other polar nucleus to form a nucleus with three nucleoli—one small and two large (Fig 1*d*) Some instances were found of divergence from the above normal conditions for example there would be in the centre of the sac one nucleus with one large and one small nucleolus, and another nucleus with one large and two small nucleoli (Fig 2*a*), or there might be altogether four or five small nucleoli (Fig 2*b* *c*), but always at this stage the large nucleoli numbered two The inference from the above is that sometimes there are more than two sperms to be found in the sac There was never any indication that more than one sperm became associated with the egg

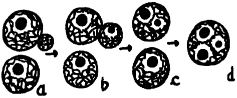

Fig 1 Triple fusion (diagrammatic) (*a*) First contact of sperm with one of the two polar nuclei (*b*) sperm attains the resting condition (*c*) sperm and one polar nucleus fused (*d*) final fusion with second polar nucleus

Ishikawa[2] discussing two cases of the presence of three sperms in the embryo sac of *Œnothera*, and other cases of polyspermy reported by other workers, considers that there are two possible sources of the extra sperm that more than one pollen tube discharges into the sac, or that more than two sperms are produced by the one male gametophyte The former of these two possibilities is favoured in the case of *Acacia Baileyana*, in view of the following facts

In several instances two pollen tubes have been seen projecting from one ovule long after fertilisation, and in at least two cases two pollen tubes were traced across the nucellus to the embryo sac at about the time of fertilisation The pollination unit is a pollinium of sixteen pollen grains There are from ten to twelve ovules (mostly twelve) in the carpel The ovules at the time of fertilisation are naked Without the restriction of a micropyle, and with four surplus pollen tubes it is reasonable to expect that occasionally two pollen tubes would enter an ovule simultaneously Moreover two pollinia have in several instances been found germinating on one stigma, their thirty two pollen tubes providing two tubes for each ovule with a surplus of eight In one case, three pollinia were seen on one stigma, when the forty-eight pollen tubes would provide four tubes for each ovule There is every reason therefore to expect polyspermy Navashin and Finn[3] record in chalazogamous *Juglans* as many as five pollen tubes to one ovule, and three pairs of sperms (one pair having already performed fertilisation) in one sac, with another pair about to be discharged into it !

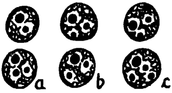

Fig 2 Multiple fusion (diagrammatic) As stage (*c*) in Fig 1 (*a*) Two polar nuclei and three sperms (*b*) two polar nuclei and four sperms (*c*) two polar nuclei and five sperms

Search for the extra sperms in the sac of *A Baileyana* at the time of fertilisation revealed two ovules containing structures that might be so interpreted, and one ovule showing possibly two tube nuclei at a stage after fertilisation was complete

Further evidence should come from chromosome numbers in the endosperm The haploid number is 13 In one endosperm a branched metaphase plate is regarded as showing 91 (7*n*), or 104 (8*n*) chromosomes, according to two possible interpretations of the structures (Fig 3*a*) Only large numbers were seen in the divisions in that endosperm In another endosperm, were one metaphase of 52 (4*n*) chromosomes (Fig 3*b*) and a late prophase and early anaphase estimated to represent 13 (*n*) chromosomes each (in this case one of the sperms or a polar nucleus would have divided without fusion)

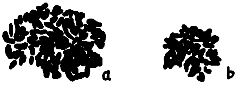

Fig 3 Metaphase plates in endosperm × 1650 Drawn from two different endosperms. (*a*) Branched plate Chromosomes on vertical branch, appearing as 12 pairs of half chromosomes are stippled There are about 91 or 104 chromosomes according as to how other paired structures are interpreted. (*b*) 52 chromosomes

From what literature is available to me here, it seems that even where polyspermy is recorded or discussed, it is only in connexion with fertilisation of the egg But in *Acacia Baileyana* I have seen no suggestion of such an occurrence polyspermy being indicated only in connexion with the endosperm The problem will shortly receive detailed attention as an abundance of suitable material is available here in the Acacias

Chemistry of the Red and Brown Algæ

IN view of the fact that a study of the literature on the red and brown algæ revealed considerable uncertainty as to whether true cellulose occurs in these plants the following seaweeds were examined for cellulose by the usually accepted methods — among the red algæ, *Corallina officinalis Bostrychia scorpioides*, *Chondrus crispus Rhodymenia palmata* among the brown algæ *Laminaria saccharina L digitata*, *Fucus serratus F vesiculosus Ascophyllum nodosum*, *Pelvetia canaliculata* and *P canaliculata* forma *libera*

The crude fibre was obtained by boiling alternately with dilute sulphuric acid and dilute caustic soda, washing the product and testing its solubility in cuprammonia its reaction to iodine and sulphuric acid, and the possibility of obtaining acetyl cellulose By these tests the presence of cellulose was established in every plant examined A full report of this investigation will appear in due course in the *Annals of Botany*

Specific Resistance of the Interior of the Red Blood Corpuscle

MEASUREMENTS of the electric impedance of suspensions of red corpuscles in serum, up to 16×10^6 cycles/sec, give for the specific resistance of the interior of the corpuscle (sheep, rabbit, chicken) 140 (± 10 per cent) ohms at 20° C This value is about twice that of the serum The value is lower than that previously derived[1] from measurements up to $4\ 5 \times 10^4$ cycles/sec, the difference being due to the inaccuracy of the extrapolation from these comparatively low frequencies The low value of the resistance of the interior of the corpuscle as compared with that of the serum is chiefly accounted for by the non conducting bulk of the hæmoglobin

Thermal Metamorphism around the Ballachulish Granodiorite

FROM recent studies of the metamorphic rocks lying within the aureole of the Ballachulish granodiorite it has appeared that there are present there most of the types of hornfelses listed in Goldschmidt's classification Derived from these are also silica poor types in which corundum and spinel are common Hypersthene has, however not been identified in any of the hornfelses which have been examined up to the present

There is definite evidence that the contact margin of the granodiorite has undergone some contamination by assimilation of the country rocks This is shown by the presence of cordierite in specimens of the granodiorite from the contact It is also noteworthy that hornblende does not appear in these rocks, biotite is alone present and resembles more the red brown haughtonite variety of the metamorphics than the greenish brown variety common to the normal granodiorite Since it appears that the igneous rock has assimilated material from the surrounding schists etc it is probable that the hornfelses have received something in exchange from the granodiorite From a mineralogical examination of the rocks there are indications that, while the granodiorite has become richer in alumina and potash the hornfelses have received lime and magnesia It is proposed to carry out a number of chemical analyses which may definitely establish the details of the suspected interchanges of material

The Theory of Vision

THE view that the stimulation of the cones of the retina is indirect and takes place through the photochemical decomposition of the visual purple by light seems to be proved and a fact How can the colourless transparent cones be directly stimulated by light? How does this direct stimulation agree with the laws of photochemistry? According to Grotthus s law, no effect can be produced by light unless it is absorbed

Occurrence of the Floating Barnacle in British Waters

ORTON and Rawlinson record, in NATURE of March 17, the occurrence of *Lepas fascicularis* and *L pectinata* on the Cornish coast in the summer of 1933 As they state that the latter has been recorded only about five times in British waters since 1803, it is worthy of record that several specimens were taken on a box found floating off Port Erin I O M, in April 1933

Research Items

Eskimo Rock-Paintings. Miss Frederica de Laguna in the course of her recent investigations among the Eskimo of Alaska discovered at Cook Inlet in the south west of Alaska a number of rock paintings in rock shelters which she has recently described (*J Soc Américanistes*, Paris, N S , 25, fasc 1) No similar rock paintings are known to occur elsewhere among the Eskimo and they have an individual style which differentiates them from the petroglyphs found among the Eskimo of south east Alaska and among the Indians of the interior of British Columbia The paintings here described are from four shelters of which three are on Kachemak Bay and the fourth in Tuxedni Bay on the western side of Cook Inlet The drawings are in silhouette in red hæmatite mixed with fat Some seem to have been made with the finger or a stick others with a finer instrument Except in one instance (Sadie Cove) there is no effort at composition, nor are all the figures on the same scale Among the subjects represented are men boats with occupants, birds, of which the species can sometimes be distinguished whales (possibly), animals wounded by lances seals and a pregnant woman The object of the paintings does not seem to have been purely artistic as they are never situated near habitations Various explanations were offered by the Eskimo, such as that they were intended to convey information about game and hence they were made on a small scale and well hidden so that the information should not be available for those for whom it was not intended Another explanation connected them with the hunting rites of the sorcerer whale hunters, who use the fat of human victims as poison for their lances On the other hand, it is pointed out that the Indians of British Columbia make rock drawings as a record of initiation rites or of objects seen in their visions

Indian Pearl Oysters Dr Baini Prashad and Mr Jnanendra Lal Bhaduri, after a prolonged study of the true pearl oysters of India, recognise five species, all belonging to the genus *Pinctada* , these are *P margaritifera*, *P vulgaris*, *P chemnitzi*, *P anomioides* and *P atropurpurea* ('The Pearl Oysters of Indian Waters" *Rec Ind Mus* , June 1933) The chief specific characters used are the amount of convexity of the valves, the length and form of the hinge margin, the presence or absence of teeth and the colour of the shells Many of Jameson's varieties are done away with, making the classification considerably simpler There is an enormous amount of variation in each species Most of them have a very wide distribution, shells from different localities, and even from the same area, often varying much in form, outline, thickness of valves and colour In addition to the diagnostic characters of the species, measurements of a number of shells from various localities are given to show the range of variability in shape and sizes

Crabs of the Genus *Parapinnixa* Steve A Glassell in a paper, "Notes on *Parapinnixa affinis* Holmes and its Allies" (*Trans San Diego Soc Nat Hist* , 7, No 27 , 1933), describes *Parapinnixa affinis*, hitherto only known from a single female specimen found by Holmes and one unpublished record of a male and female by Mr G E MacGinitie, from California The present author has collected a series of both males and females at San Diego, California This crab lives as a commensal in the tubes of a marine worm, now being described as a new species of *Amphitrite* This worm builds a slimy tube of mud and sand among clumps of shells and weeds at about mean low tide level in situations protected from the full force of the waves Mr Glassell recognises three species of *Parapinnixa* from the Pacific *P affinis*, *P nitida* and *P yokoyai*, and three species from the Atlantic *P hendersoni*, *P bouvieri* and *P beaufortensis* In a recent paper by Tune Sakai, however, A New Genus and some Species of Crabs from Simoda" (*Sci Rep Tokyo Bunrika Daigaku* (B), 1, No 12 , 1933), a new species from the Pacific is described, *Parapinnixa asiatica*, obtained near Simoda attached to seaweed *Parapinnixa nitida* was found living as a commensal with a terebellid worm *P yokoyai* which is a new name given to the Japanese species called *affinis* by Yokoya is very like the new species from Japan but apparently differs in certain features, notably the shape of the telson The first zoeal stage of *P affinis* hatched from an egg in the laboratory is figured, showing a resemblance to that of *Pinnotheres pisum*

Detection of Tubercle bacilli The *Edinburgh Medical Journal* of March (41, No 3) is a tuberculosis number', and Dr Alfred Emslie records attempts made to detect the tubercle bacillus in the blood stream in cases of pulmonary tuberculosis Contrary to Loewenstein of Vienna, who claims a high percentage of positive results in his cases, Dr Emslie failed to detect the presence of tubercle bacilli in the blood of 34 known tuberculous patients either by cultures or by animal tests This negative result accords with the experience of most observers other than Loewenstein who have sought for tubercle bacilli in the blood of tuberculous patients (see Prof Wilson s critical survey of the literature, Medical Research Council, Special Rep Series, No 182, Tuberculous Bacillæmia ')

Revision of the *Ceratopsia* Prof R S Lull, in a memoir of the Peabody Museum (vol 3, part 3, 1933) has given a revision of that group of the dinosaurs known as the *Ceratopsia* Much work, both in collecting and in investigation, has been done since the earlier account of the group by Hatcher published in 1907, a few years after his death, which dealt with the American species In the present memoir the author brings our knowledge up to date by taking into account not only fresh material found in the United States but also the discovery of *Protoceratops* by the American Museum expedition to Mongolia, a form which throws much light on the earlier evolution of the group Besides the description of the known species and a revision of them, the memoir deals with various other aspects of the family The history of discoveries, the geographical and geological distribution, the morphology of the skull and skeleton, the brain and the evolutionary changes that have taken place during the course of phylogeny are subjects that receive treatment A gradual evolution along several parallel lines has taken place, some of short duration, others longer, and culminating in the various species of the genera *Triceratops* and *Torosaurus* These lines are not all definitely proved and in this the memoir must be considered as an interim report to be corrected at some future date The results so far seem to show a similar evolutionary process to that shown by Osborn to have occurred in the Titanotheres, a principle applicable perhaps to vertebrates generally Works of this kind that bring up to date and summarise our knowledge of various groups of animals are of great use, not only to the specialist but to the general reader as well

Protein Building in Plants A problem which continues to excite interest is that of the methods by which proteins may be built up in plants and particularly, the nature of the raw materials used The passage of years has not seriously affected the view that asparagine may be either a key substance in protein synthesis and degradation or else closely related to the key substance O Loew (*Z angew Bot* 15 518, 1933) now suggests that the process of protein synthesis may start from the reduction of asparagine to the di aldehyde of aspartic acid, $CHO\,CH_2\,CH\,NH_2\,CHO$ He directs attention to the case with which a substance of this type could be further condensed to its lability and to the possible methods by which it could be derived An essential part of the theory is the formation of labile condensation products and microchemical evidence is given as to the existence of materials of the type postulated in certain epidermal cells

Botrytis Disease of Lettuce A very complete account by Dr M M Abdel Salam of the severe disease of lettuce caused by the fungus *Botrytis cinerea* has recently appeared (*J Pom and Hort Sci* March 1934) It is shown that the disease may produce a variety of symptoms—a collar rot (red leg) in spring, lesions on the stem, main veins, or upper leaves (head rot) through the summer, or outright killing if the plant is also attacked by frost in winter The disease is most severe on seedlings over wintered in a cool frame and higher temperatures diminish its effects High humidity favours attack The variety Lee's Immense proved resistant to the fungus, though there was a general tendency to outgrow the damage in spring Steeping the seedlings in 0 5 per cent Uspulun or Nu green solutions for half an hour or an hour gave promising results as a means of control

Sterility in Plants Prof R Ruggles Gates has prepared a concise summary of present-day knowledge of sterility in plants (*J Roy Hort Soc*, 59 141 Feb 1934) Beginning with the methodical observations of Charles Darwin, the author traces the growth of knowledge on plant sterility until recent times Investigations by Prof East provide a reasonable working hypothesis by way of explanation of many problems of sterility Definite sterility factors have been discovered for various species of *Nicotiana*, and fertilisation can only be effected between germ cells having different combinations of these factors This discovery has been put to practical use by Dr A B Stout, working with lilies, Messrs Williams and Slow for red clover and Messrs Crane and Lawrence for cherries Gardens must be planned to include more than one "sterility group" if they are to be productive Recent knowledge seems to confirm Darwin's original observations, for Correns described in 1928 a case of self sterility in *Tolmiea Menziesii* where each plant was self-sterile, but fertile with every other plant of the species

Microseisms in Manila. In a recent paper (*Beit Geoph*, 40, 268, 1933), Father Repetti discusses the microseisms recorded in the Observatory of Manila. To a great extent he finds, they are due to the rhythmical beating of heavy waves on the coast of Luzon, for they appear and disappear with the winds that raise the waves Sometimes, they are clearly connected with passing typhoons Partly, the very conspicuous tremors that are then seen are due to the waves raised by the wind of the approaching typhoon But, when it comes near Manila, the oscillations of the crust produced by the pumping effect at the centre of the typhoon are superposed on those set up by the sea

A New Recording Densitometer The Société Genevoise d Instruments de Physique (address of British agents—5/6, Brettenham House, Wellington Street, W C 2) has issued a description of a new recording densitometer which is said to show a sensible improvement over all other instruments serving the same purpose Its main principle is the usual one of allowing a greatly reduced image (in this instrument so small as to make a primary slit unnecessary) of a glowing filament to travel along the plate to be analysed, the transmitted light, after passing through a slit being received by a potassium photoelectric cell Among the special features of the instrument are a very high speed of automatic recording and a sharp response to small details of the plate, made possible by amplifying the photo electric current so that it can be measured by a sturdy milliammeter of short period instead of an ultra sensitive galvanometer of long period The apparatus can be operated in full daylight and the recordings are absolutely precise, being independent of mechanical parts such as gears or measuring screws Magnifications of 3 4 5 8 10 15 20 and 50 times are obtainable, and the recording is performed at a speed of 15 cm per minute on the diagram The cost of the instrument, which is not given, is said to be considerably below that of similar instruments

Mean Lives of Excited Atoms J H E Griffiths (*Proc Roy Soc* A Feb) has investigated the mean lives of several excited states of the neon atom The atoms are excited in a glass spectrum tube by a high frequency oscillator, and the light is passed through a nitrobenzene Kerr cell between Nicol prisms To make comparative measurements of the decay times of the different spectral lines, the Kerr cell was excited by the oscillator through a phase changing circuit, but since the phase relation between current and voltage in the discharge tube is unknown a different method was employed to determine absolute values The discharge tube and Kerr cell were connected in series and the light path between them was varied by using a movable mirror The number of excited atoms and the intensities of the lines are both periodic, with a frequency twice that of the oscillator From the positions in the maxima of the transmitted light, it was concluded that the lives of the excited states varied from 4×10^{-8} sec to 20×10^{-8} sec The experiments on several lives with a common upper state showed satisfactory agreement With a wide tube it was found that there was an appreciable lag between maximum current and maximum excitation, but this lag was not observed with a narrower tube At the higher pressures the depth of modulation of the light was small with the wider tube, and it seems that electrons disappear from the discharge mainly by diffusion to the walls

Evolution in the Expanding Universe

A LECTURE was delivered by the Abbé G Lemaître, professor of mathematics in the University of Louvain, at Armstrong College, Newcastle upon Tyne, on the subject of "Evolution in the Expanding Universe" before a joint meeting of the Durham University Philosophical Society and the Newcastle Astronomical Society on February 12 Dr R A Sampson, Astronomer Royal for Scotland, occupied the chair, and the speaker was welcomed by Sir William Marris

The age of the universe, calculated from the observed recession of the nebulæ, is about $2{\cdot}4 \times 10^9$ years, whereas the ordinary theory of stellar evolution requires about 10^{13} years If the matter in the universe were evenly distributed, the density would be 10^{-30} gm /cm ^{3} The correction of Newton's law given by Einstein may be regarded as equivalent to a density, of negative sign, associated with space, and if accompanied with a positive pressure the system would be invariant in the Lorentz transformation This density, a cosmical constant, works out at -10^{-27} gm /cm ^{3} and as this is greater than the average density of matter, the effect produced would be, in general, a repulsion

Taking any point as centre, the motion for a nebula at distance r is represented by

$$\left(\frac{dr}{dt}\right)^2 = -h + \frac{2Gm}{r} + \frac{\lambda}{3} c^2 r^2$$

The density of a vacuum is $\rho^0 = \lambda c^2/4\pi G$, where G is the gravitational constant Over large (spherical) areas this is to be regarded as a map in which distances normal to the radius vector are real but those along it are in a scale $\sqrt{1 - h/c^2}$ where h is the energy constant in the equation of motion (h varies as r^2, and m as r^3) For some value $h = c^2$, the scale becomes zero and the map ends, but actually antipodal points are the same, like the points at the sides of a map on Mercator's projection

Suppose now that the universe once consisted of matter with an average density greater than the critical, but with an initial velocity sufficient to carry it over the critical radius, this gives the proper expansion When r is put equal to infinity in the above equation, only the last term is important, so that the velocity squared is equal to $\lambda/3\ c^2$, from which the cosmical constant may be obtained Actually, there must have been fluctuating density in the initial state, and areas in which the separation of matter was less than the mean In these, the matter would eventually fall back producing collapsing regions, more rarely, equilibrium areas would occur which would divide into collapsing regions The first might produce nebulæ, the second, nebular clusters If these areas coalesce, some loss of kinetic energy must take place due to encounters, and the original diffuse matter would agglomerate into stars

A nebula has a mass of about 10^9 suns; its radius at critical density would be 10^5 light years, the order of diameter is now about 1,000 light years The loss of kinetic energy will be

$$\frac{3}{2} G \frac{N^2 m^2}{R}$$

where N is the number of stars, m the average mass of each, R the radius The gravitation energy of a star is

$$\frac{3}{2} G \frac{m^2}{r}$$

where r is the radius Multiplying this by N gives the total and dividing $Nr/R = 6 \times 10^{-2} = 6$ per cent of the gravitation energy of the stars This energy becomes heat, and the heat content of stars is of this order

Regarding clusters, here also the right order is obtained They should have the same densities, and this should be about the critical density If N be the number of nebulæ in the cluster, m the mass of each,

$$Nm = c \times D^3 d^3$$

where D is diameter, and d angular diameter in degrees, and $c = 0{\cdot}155 V^2$ where V is the velocity of recession at 1 megaparsec The observations of Hubble and Shapley give figures of the right order (10^9 suns)

Salmon and Trout Disease

IN the year 1911, cases of a hitherto unrecognised disease, causing death of large numbers of fish of various kinds, were reported from six rivers in the south west of England This was the first official record in Great Britain of the occurrence of furunculosis, a bacterial disease that has spread to many rivers in England and Wales and is now prevalent throughout Scotland Serious outbreaks occurred in the Conway and Coquet districts in 1926 when salmon and migratory trout were attacked, and in the Kennet in 1924 and 1925, when the valuable brown trout fisheries suffered, and in recent years the disease has continued to spread While in 1932 there was a considerable abatement in the number of serious outbreaks in English rivers, in Scotland conditions were nearly as bad as ever

The monetary loss entailed by the spread of this disease must be large, since in one river over a period of six years the estimated loss was £1,400, and in another larger river it was £2,000 in three years But apart from this loss, there must be a more serious loss in the depletion of the breeding stock The alarming increase in the number of outbreaks led to the setting up of a Furunculosis Committee in 1929, a copy of the second interim report of which is now before us * The report indicates the satisfactory progress of research into the problem, carried out by a number of workers chiefly at the Bacteriological Laboratory of the University of Edinburgh, among whom Mrs Isobel Blake deserves special mention

Furunculosis is a disease caused by a bacillus, *B salmonicida*, which infests salmon, trout and coarse fish, in advanced stages of the disease there may be lesions in the muscles, but in many cases death occurs without any obvious external symptoms and the cause can only be definitely proven by bacteriological examination.

---

* Second Interim Report of the Furunculosis Committee (Edinburgh and London H M. Stationery Office, 1933) 2s 6d net.

Once established in any locality, the spread of the disease is practically uncontrollable. Experiments have shown that infection can be water-borne or carried in food, and that the presence of fish that have died from the disease may be a serious source of infection. The disease is not brought in from the sea, and migratory fish may be infected in the fresh water sooner or later after they have left the sea; the fish appear to be highly susceptible when they first enter fresh water.

The most dangerous source for the spread of the disease is the occurrence of carriers in which the bacilli are present in small numbers only and are located in the kidneys. Such fish may live apparently unharmed for a considerable time but generally fall victims themselves in the end, not without, however, infecting other members of the community before their death. It has been found that wounds and scratches render fish especially liable to infection.

It is probable that the disease has been spread over so large an area by the practice of stocking rivers with eggs and fry from other localities and from fish farms. It has now been shown that the eggs can be sterilised with dilute solutions of acriflavine.

Experiments and observations in Nature show that the outbreaks of the disease are controlled by temperature conditions, a temperature within a range of about 55°–66° F. apparently being necessary for its spread and development when the fish are healthy; cases have been reported of the occurrence of the disease at lower temperatures among fish in poor condition after spawning. Overcrowding is a further predisposing cause for outbreaks and it is noticeable that where barriers occur to cause the congregation of fish awaiting flood water the disease is prevalent; where possible, therefore, such difficulties in the paths of the fish on their upstream migrations should be removed. The reporting of suspected outbreaks as soon as possible is of the utmost importance, as is also the quick removal of all dead infected fish.

Of even greater importance at this stage is the necessity for the passing of legislation whereby action may be taken to reduce risk of further dissemination to a minimum. In December 1929 an interim report was submitted in which a system of control was urged so that importation of live fish might be controlled and notification of outbreaks of disease made compulsory, and that there might also be power of control both over fish farms and over open rivers declared to be infected. It is to be hoped that the necessity for such action in the near future will receive serious consideration before the plague has assumed such alarming proportions as has been allowed with the musk rat. It is, however, evident that one of the main difficulties in controlling the disease is that the symptoms are not always obvious and that identification necessitates sending the corpses to bacteriological laboratories for examination, and, furthermore, that they should arrive before decomposition has set in.

A New Experimental Phonetics Laboratory

WITH the advent of the talking film, the recording of speech has recently received considerable attention; but, as at the time of the invention of the phonograph, more interest is shown in commercial circles in the entertainment possibilities of the new electrical methods of speech recording and reproduction. In experimental phonetics the older mechanical methods still predominate. At Armstrong College, Newcastle-upon-Tyne, with the support of Prof. W. E. Curtis and Prof. W. L. Renwick, an investigation was undertaken by Mr. R. O. L. Curry, Noble Memorial Scholar, of the available methods of speech recording with the object of seeing how far these were suitable for classifying speech sounds, particularly those of local dialects. The work of making and testing different types of apparatus has been so successful that the Council of the College, mindful of the importance of the investigation, has granted space in a newly acquired building for a phonetics laboratory to house the apparatus, and in which records may be taken under conditions free from noise and vibration.

The laboratory looks out upon an empty court and the windows on this side are sealed and provided with dark blinds. The floor is of concrete and the partition walls are 1 ft. thick, so that it was thought unnecessary to introduce sound-insulating material except on the door, which is faced on the inside with a layer of Newall's Asbestos Blanket. A ventilating shaft in the thickness of the wall leads out to the roof at a point sheltered from street noise. To make doubly sure that no 'ground noise' shall reach the recording apparatus, the microphones are placed in a double-walled insulated kiosk of the telephone cabinet type. There is also provision for the development of photographic plates.

The recording devices which are at present available in the laboratory are as follows:

(1) A kymograph, namely, an instrument in which the pressure variations which occur in the mouth, nose and throat during speech can be severally communicated to membranes provided with styles which make traces on a revolving drum. Owing to the damping and distortion introduced by the recording mechanism this instrument is useless for obtaining exact traces of speech sounds, but is fully satisfactory for recording the relative time intervals involved in speech sounds, and for determining the relative extent to which different parts of the vocal apparatus contribute to the sound, as, for example, in the nasalisation of a vowel or a consonant.

(2) An Einthoven string galvanometer, which, while capable of giving accurate traces of vowel sounds, is too heavily damped with regard to frequencies above 6 000 cycles/sec. to record correctly the fricative high-pitched sounds associated with many of the continuant consonants. This is, in fact, the principle of the apparatus by which most talking films are made.

(3) A cathode ray tube. This is the most effective instrument of all and is capable of delineating the wave form at all frequencies to which the microphones are able to respond. For visual examination of vowel sounds a sweep circuit is used, which allows of a single wave pattern being 'held' on the screen; otherwise a moving film camera is used, capable of taking photographic records of the to-and-fro motion of the spot on the fluorescent screen at 6 ft./sec., a rate which permits of the recording of the high frequency stopping and starting noises that are characteristic of the consonants.

(4) There is also an electric gramophone recorder for making dialect gramophone records, and a jet tone apparatus for studying the action of the vocal organs in speech

The first work of the laboratory, which is under the joint supervision of Mr H Orton, of the English Department, and Dr E G Richardson, of the Physics Department, will be to obtain definitive pictures of the standard English speech sounds This work is, in fact, almost completed Records of dialect speakers will then be taken for the purpose of the main object of the laboratory, which is the comparative philology of the region in which the University of Durham lies In this connexion, room is provided elsewhere in the College for card indexes of local variants in pronunciation

For the benefit of others who may be intending to take up similar work, it may be mentioned that the cost of the equipment of a laboratory such as this is quite moderate Excluding the string galvanometer (which is not essential), the whole of the equipment has cost less than fifty pounds, although it is true that this does not include the cost of the labour of assembling the apparatus

Chemical Society's Mendeléeff Commemoration

THE centenary of the birth of Mendeléeff was commemorated by the Chemical Society on April 19 when Lord Rutherford delivered an address at the Royal Institution on The Periodic Law and its Interpretation"

About the period 1860–70, accurate atomic weights and chemical data were available for the known elements, and the time was ripe for some connecting generalisation The conception of a periodicity in properties when the elements are arranged in the order of their atomic weights was advanced tentatively by Newlands in 1864 Mendeléeff was the first, in 1869, to enunciate the law clearly, to perceive its utility in correlating and even correcting the recorded chemical properties of the elements and to make from it predictions which might be verified by later investigation

Mendeléeff's first table, published in 1871, bears a remarkable resemblance to that of the present day He perceived the true place of the transition elements in the scheme, and did not hesitate to reverse the apparently discordant order of iodine and tellurium Where his table demanded the presence of then unknown elements he ventured to predict their properties, his prophecies being strikingly fulfilled by the subsequent discovery of scandium, gallium and germanium

The discovery of argon and its congeners by Ramsay, at the close of the century, led not to an alteration, but to a widening of Mendeléeff's scheme, the inert gases falling naturally into a group of zero valency and forming a transition between the halogens and the alkali metals During this period, the Periodic Law lacked any theoretical background which might lead to its interpretation Sir J J Thomson's recognition of the electron as a constituent of all atoms of matter, in 1897, first led to the conception of the electrical structure of matter

Lord Rutherford himself has been intimately connected with much of the subsequent development in this field From consideration of the scattering of α particles by heavy atoms, he was led to the nuclear theory of the atom, according to which the mass of the atom is concentrated in a minute, positively charged nucleus, the charge on which is proportional to the atomic weight of the atom The conception that the nuclear charge and ordinal number of an element might be the same was applied by Bohr in his theory of spectra It was brilliantly verified by Moseley's work on the X ray spectra of the elements, which fixed the true order of the elements, and showed that only 92 exist from hydrogen to uranium Of these, only one—No 85—still awaits discovery

The recognition of atomic number rather than atomic weight as defining the properties of the elements cleared away the apparent discrepancies in Mendeléeff's table It has been found that most of the elements are actually complex, consisting of isotopes having the same nuclear charge but different masses The chemical properties of isotopes, depending on nuclear charge, are identical properties depending on mass may differ sufficiently to render separation possible, as is the case with hydrogen and lithium

The explanation of the Periodic Law must lie in the arrangement of the outer electrons Bohr's conception of quantised planetary orbits has been developed by the new wave mechanics to give a complete picture of atomic properties The rare gases have highly symmetrical, tightly bound configurations Addition of successive electrons leads to the occupation of the next group of orbits, and runs parallel to the observed chemical properties of the elements A periodic pattern is thereby obtained, repeating after each inert gas, in which the transition elements and rare earths find a natural place About the structure of atomic nuclei, little is yet known the recognition of any periodicity with increasing nuclear charge awaits the discovery of the future

Increase in Temperature due to Solar Radiation

PROFESSIONAL NOTE No 63 of the Meteorological Office, the title of which is "Maximum Day Temperatures and the Tephigram", by Lieut - Col E Gold, is a discussion of the problem of estimating the probable rise of temperature in the course of a single day during clear weather on account of the solar radiation, with the aid of the 'tephigram' of Sir Napier Shaw

In the 'tephigram' the rectangular co ordinates are temperature and entropy, and any closed area, corresponding with a cycle of changes of a portion of the atmosphere, represents a definite amount of energy Isothermal lines and dry adiabatics are represented respectively by vertical and horizontal lines, and moist adiabatics, corresponding with saturated air that is rising and expanding, and is in consequence having its entropy increased by the energy released by condensation of water vapour, are represented by sloping lines that become more nearly horizontal at low temperatures owing to the diminished capacity of air for water vapour at such temperatures This form of diagram is in use in the

Forecasting Department of the Meteorological Office and the note, apart from the intrinsic interest and importance of the subject should be helpful to forecasters when interpreting the significance of the physical state of the atmosphere revealed by observations made in aeroplanes equipped with meteorological instruments

A discussion of the energy equivalent of 1 cm on this diagram leads up to a consideration of the amounts of radiation received in different months and the heights up to which the dry adiabatic lapse rate can be brought into being in each case, given isothermal conditions initially

When passing on to consider what proportion of the total incoming radiation may actually be available for warming the atmosphere allowance having been made for the increased radiation from the earth s surface the incoming diffuse radiation of short wave length the reflected radiation and for the heat absorbed in evaporating water from the surface the author is on difficult ground An estimation of the last item for example has apparently been based entirely on figures for the evaporation from water tanks the relationship between such figures (practically the only data available) and those representing the average evaporation by day at the season in question from unit area of the earth s surface is very much a matter of speculation The table on p 8 giving the various allowances suggests however that in summer this may be a very important item A suitable warning in regard to the uncertainties of *all* these allowances would not have been out of place in order to prevent the uninitiated from thinking that the difficult problems under discussion have reached anything approaching an exact quantitative solution E V N

University and Educational Intelligence

BIRMINGHAM —The University has decided to institute a Department of Industrial Hygiene and Medicine and arrangements are being made with the view of opening it on October 1 1934 It is believed that this is the first department of this nature to be established in a Medical School in Great Britain The research work contemplated includes the investigation of the deleterious action on work people of the materials they work with and methods of prevention , the training of medical men to advise employers as to methods by which the number of certain types of accidents may be reduced the selection of employees for various kinds of work and improving the hygiene of factories It is probable that the University will grant a diploma to those who complete the course successfully

CAMBRIDGE —The Sheepshanks Exhibition for 1934 has been awarded to C G Pendse of Downing College

The Linacre Lecture will be delivered by Sir Henry Dale, director of the National Institute for Medical Research on Saturday May 5 at 5 p m , in the New Museums The title of the lecture will be Chemical Transmission of the Effects of Nerve Impulses

LONDON —The degree of D Sc in chemistry has been conferred on H E Cox (private study) for ten independent publications and four conjoint subsidiary contributions relating to the chemical examination of furs in relation to dermatitis and food analysis

APPLICATIONS for the Bayliss Starling Memorial Scholarship tenable at University College London W C 1 must be sent to the College Secretary not later than May 12 The annual value of the scholarship is £120 with exemption from tuition fees The scholar will be required to follow a course of study approved by the Jodrell professor of physiology involving a training in the principles and methods of research in physiology or biochemistry or both

Science News a Century Ago

King s College London

On April 30 1834 the annual court of governors and proprietors of King s College was held for receiving the report of the council for the previous year The Archbishop of Canterbury presided The report stated that the council had previously expressed some doubts as to whether it would be possible to complete the river front owing to the considerable sums promised by subscribers not being forthcoming A meeting however had been held at which it was agreed to make an appeal to the friends of the institution and the consequence was that in advances of ten per cent on the shares and in subscriptions and donations a sum of £7 297 17s had been received During the year there had been 104 regular and 171 occasional students in the senior department 66 regular and 175 occasional students in the medical class and 404 students in the junior department A class of associates had been instituted The College had never before been so prosperous Two additional schools had been added so that there were now seven schools in the metropolis acting in union with the College The receipts for the year were £16 197 11s 6d and the expenditure £12 446 14s 5d leaving a balance of £3 750 17s 1d besides £4 000 in exchequer bills

Friday Evening Meetings at the Royal Institution

At the annual meeting of the members of the Royal Institution on May 1 1834 the Visitors commented on the increased membership and improved financial position shown by their Report This satisfactory state of affairs they attributed largely to the interest excited by the Friday evening meetings which had been begun about 1825 and had become a regular feature of the Institution s activities The Visitors reminded members how deeply they were indebted for these advantages to the unwearied exertions important discoveries and happy illustrations of one who has contributed the chief attractions to the meetings in question The reference is to Faraday Not only had he given a considerable number of the discourses himself but from the beginning had acted as secretary of the small committee charged with the duty of arranging the Friday evening discourses That their success depended almost entirely on his activities may be inferred from a letter written to Faraday in 1839 in which W T Brande then the senior professor at the Institution, regretted that he could not help at a time of emergency He wrote You know how sad a figure I cut on those occasions and as to the tact requisite for their general management and arrangement I candidly confess I have it not

Belgrave Literary and Scientific Institution

On Saturday, May 3, 1834, as reported in the *Times*, a public meeting was held to give effect to the arrangements of the provisional committee of the Belgrave Literary and Scientific Institution, and for opening the Institution for the accommodation of members Earl Fitzwilliam presided and the report of the committee said that the foundation of the Society had been laid by voluntary subscriptions of books, and that it was intended to open No 30, Sloane Street for the purposes of the Institution Dr Lardner and others had offered to give lectures gratuitously, the Duke of Sussex had consented to accept the office of patron and Earl Fitzwilliam that of president

A New Orchid

Probably the most important account in *Curtis' Botanical Magazine* for 1834 is that of the first flowering of the new orchid *Epidendrum bicornutum* from Trinidad, which occurred in April 1834 at Wentworth Gardens, the seat of Earl Fitzwilliam, under the care of Mr James Cooper, the celebrated orchid grower The specimen is described (p 3332) as having produced large and highly fragrant blossoms, which smell like the Persian Iris This plant was introduced into England by Mr John Sheppard, curator of the Liverpool Botanic Gardens, marked as "Cattleya n sp" It had many points in common with that genus, especially in its general habit and the large flower, but differed remarkably in the labellum and the shortness of the column The specimen was sent to Prof Lindley who replied to the editor 'Your Trinidad orchideous plant is certainly a new species but I think it can not be separated from Epidendrum The only distinction between it and that Genus consists in the labellum being distinct from the column but you will find various degrees of separation between those parts in *E asperum*, *venosum*, *vitellum* and *bidentatum* which nobody can doubt are genuine Epidendra Should you, however, be of opinion that it nevertheless must form a new Genus, its character will have to depend upon the large size of the petals and the slight adhesion of the sepals to their base The latter is however a falacious character and the former occurs in what I consider true Epidendra"

Other Flower Records

Further interesting records of the flowering of rare orchids and other plants introduced into Great Britain occurred in April 1834, mostly at Kew Gardens In *Curtis' Botanical Magazine* (p 3401, 1835) is described the first flowering at Kew of *Pteostylis acuminata*, the acuminated pteostylis (Orchideæ), of a singular Australian genus introduced by Mr Cunningham from Port Jackson in 1827 *Acacia elongata* (Leguminosæ) a slender and beautiful species from the Blue Mountains of New South Wales and the interior to the west of Port Jackson, originally discovered during the first expedition of Mr Oxley to the Lachlan River in 1817 and introduced into England in 1823, when the plants were received at Kew, was in full flower at the latter gardens in April 1834 Another flowering record of the month, in the gardens of Mr William Christy at Clapham Road, was *Schinus molle*, the Peruvian mastick tree (Terebinthaceæ), which grew wild in Chile, Peru and Mexico The occurrence is recorded, with a plate of the bloom, in the 1834 volume.

LONDON

Society of Public Analysts, April 4 GUY BARR and A L THOROGOOD Determination of small quantities of fluorides in water The reagent consists of an aqueous solution of zirconium oxychloride and sodium alizarin monosulphate The test is sensitive for 0 1 part of fluorine for concentrations up to 5 parts per million A W MIDDLETON A test for ethylene glycol and its application in the presence of glycerol The test is based upon the oxidation of glycol to oxalic acid by means of nitric acid, whilst under the same conditions glycerol yields aldehydic substances Glycerol does not interfere unless present to the extent of more than 75 per cent of the mixed alcohols, and the test is sensitive to 0 1 gm of glycol in 10 ml of aqueous solution W MATHER and W J SHANKS Detection of diamines in leather Tests are described whereby extremely small quantities of para and meta diamines can be detected in dyed and finished leathers These diamines can be extracted from leather in the cold by means of $N/10$ hydrochloric acid or 1 per cent acetic acid, and that precipitation of the extracted tannins with lead acetate does not interfere with the subsequent tests for diamines The reagents used include 0 1 per cent solutions of dimethyl *p* phenylene diamine, dimethyl aniline, aniline, *o* toluidine, *p* phenylene diamine, and *m* toluylene diamine

Royal Meteorological Society, April 18 D BRUNT The possibility of condensation by descent of air From a consideration of the variation with height of the humidity mixing ratio, it is shown that in the stratosphere condensation can occur in descending air masses which take up the temperature of their environment The fact that saturated water vapour produces condensation when expanded adiabatically while other saturated vapours produce condensation when compressed adiabatically, is discussed briefly D DEWAR An investigation of the statistical probability of rain in London The paper gives an account of an investigation of the frequency of rain at Kew, based on hourly tabulations of rainfall from 1872 to 1921 Amounts of rain were classified as heavy', 'moderate', slight', or 'no rain', according as the quantity which fell in a 6 hour interval of the day was 1 mm or more, between 0 5 and 1 mm, between 0 2 and 0 5 mm, or less than 0 2 mm The intervals were taken as early morning, forenoon, afternoon and night, each division of the day being taken to cover an interval of 6 hours Each month was divided into three periods of approximately 10 days The probability of rain of a given amount in a given interval of the day during these periods was obtained by dividing the number of occasions on which rain of that amount had fallen by the number of possible occasions A comparison between actual values and figures computed from the average probability shows that the frequency of 'heavy' rain in 6 hour intervals for individual days is distributed approximately according to a chance distribution The average probability of rain in a 6 hour interval is approximately 1 in 9 for heavy rain, approximately 1 in 20 for moderate rain, approximately 1 in 23 for slight rain CALEB MILLS SAVILLE Some rainfall variations, England and New England (U S.A) The maximum and minimum rainfall experienced during periods of from one to twelve consecutive months is similar in both localities Details are given as to the extremes of rainfall recorded at West Hartford (U S A) for periods of 1–120 consecutive months In Great Britain a run of wet years persisted before the present drought but in New England dry years predominated This marked inverse relationship held from 1868 until 1932 in the case of residual mass curves, and from 1838 until 1932 with a somewhat different set of data expressing the rainfall as 5 year means

Rewards for Scientific Discoveries

THE continued growth of nationalism during the past few years has brought clearly to the mind of many people the thought that *pace* the League of Nations and all it represents the struggle among nations will in the future as so often in the past result in the battle going to the strong and the race to the swift One consequence is that the governments of the more important nations aware of the futility of trusting to mere numbers of man power are turning more and more to the encouragement of the best minds among their own nationals in the hope that their discoveries will place their own nation in the forefront and so enable it to reap the due reward be it either in war or in peace

Although this encouragement has taken various forms in different countries and includes in most countries the granting of honours and the general esteem of the public in no country has it taken a form which is regarded as entirely satisfactory while in most countries the reward whether to workers in science or in art must be regarded as deplorably inadequate from the financial point of view In Great Britain the difficulties of the Department of Scientific and Industrial Research in the realm of science are only too apparent while the inadequacy of the reward of composers in view of the vast development of broadcasting and the gramophone is a matter for keen regret In other countries similar problems are forming the subject of most searching inquiry an example of such inquiry being the first of a series of papers which the Council of the American Association for the Advancement of Science is authorising the paper being the Report of the Committee on Patents Copyrights and Trade Marks entitled The Protection by Patents of Scientific Discoveries published as a Supplement to *Science* in January last (New York The Science Press) Extracts from the Report appear elsewhere in the present issue of NATURE

Much discussion has occurred upon the question of the patenting of scientific discoveries In an attempt to formulate a policy or agreement upon principles it may be worth while to consider first those inventions which have possible industrial uses and are patentable and whether scientific investigators should obtain patents on such inventions which have resulted from their work medical patents being for the moment excluded as presenting peculiar difficulties Many objections have at various times been raised against patenting by scientific investigators, among them, for example, being that it is unethical for scientific men or professors in universities to patent the results of their work, that publication or dedication to the public is sufficient to give the public the work of a scientific man, that patenting will lead to the debasement of research, that patents will place unfortunate strictures on other men who afterwards do fundamentally important work in the same field, and so on

After considering these and other objections, the opinion of the Committee is that the patenting of the results of research (other than medical research) which have some possible commercial importance or industrial application is highly desirable, and indeed it is difficult to understand how any opposite opinion could be held either in the United States or elsewhere

The question of medical patents is in Great Britain admittedly difficult, mainly because the preponderating weight of medical opinion is against the granting of medical patents to medical practitioners At the annual general meeting of the British Medical Association in July 1931 there was a prolonged debate which resulted in a resolution

> "That the Association approves the traditional usage in accordance with which it is unethical for any medical practitioner who discovers or invents any substance, process apparatus, or principle likely to be of value in the treatment of patients to act against the public interest by unduly restricting the use and knowledge of such discovery or invention for his own personal advantage"

It should be remembered, however, that although medical opinion in Great Britain is opposed to the patenting of medical inventions by medical practitioners, the recently revised patent law (see the Patents and Designs Acts 1907–1932, Section 38 A) permits the patenting of medical inventions by any person under rigidly defined conditions which adequately protect the public interest Whether in these circumstances it is either in the best interests of the medical profession or in the public interest that medical practitioners should hold aloof from patenting medical inventions, may reasonably, it is submitted, be open to doubt

Probably most of the discoveries made by scientific investigators cannot be protected under our present patent laws even if the investigators so desire, and there remains, therefore, the question whether the present inadequate reward of investigators in fields outside patentable inventions can be increased by any means alternative to those at present employed, for not even the most exalted scientific man can subsist solely on honours and public esteem

The brief history of alternative means which have been suggested is that before the War vague proposals were, from time to time, put forward for the protection of scientific property, that is, the property which a scientific investigator might reasonably be held to have in the whole of the results attributable to his work After the War, however, definite proposals were made and soon became an issue with the League of Nations, resulting in the adoption in 1922 by the International Committee of Intellectual Co operation of the following motion

> "The Committee, considering that intellectual property is not sufficiently protected and that scientific property particularly is at present not protected at all, entrusts a subcommittee consisting of MM Destree, Millikan Ruffini and de Torres Quevedo with the duty of examining the means by which this protection may be assured"

Western European nations weighed and pondered the issue France, Italy, Norway, Switzerland, Spain and Portugal announced in favour of the protection, while Great Britain, Austria and Germany opposed it In the United States, almost dead silence was maintained, "due probably and mainly to an ignorance of the question" (R Spencer, "Scientific Property", *American Bar Association Journal*, February 1932)

Different plans were proposed for affording protection (1) by the establishment of an international bureau, (2) by the creation of a fund contributed to by manufacturers, (3) by donation of government funds to the discoverer and (4) by the extension of the patent system to include scientific discoveries

The conclusion of the whole matter from the American point of view seems to be that no practicable and desirable means alternative to those in operation at present has been proposed It is probably the fact that in Great Britain a similar opinion is held So far as inventions form subject matter for the grant of Letters Patent, the law has been recently revised and brought up-to date in the Patents and Designs Act of 1932 Any person, be he scientific investigator, medical practitioner or otherwise is at liberty, unless as in the case of the medical practitioner he is restrained by ethical or similar considerations, to apply for the grant of a patent for any invention which constitutes a new manner of manufacture If the invention or discovery lies outside the field covered by the Patents Acts, no alternative to the present means which is practicable and desirable has been suggested, and if scientific investigators in this field are to be adequately rewarded, it seems that the only way open is for a more generous support to be accorded to them both by public and private benevolence than has hitherto been the case

---

Myths of Polynesia

Religious and Cosmic Beliefs of Central Polynesia
By Robert W Williamson Vol 1 Pp xxi+399 Vol 2 Pp vi+398 (Cambridge At the University Press, 1933) 50s net

A REVIEW of these two volumes must be the funeral oration not only of a good worker, but also of a school the best traditions of which he worthily represented Of this school Tylor may be considered the father He proceeded by culling illustrations from the whole world and in making generalisations without any strict method It was the only course open to those pioneers to whom only fragments were as a rule available They were like surveyors on the top of a mountain picking out the salient features of the landscape, indicating roughly the trace, and leaving it to others to work it out in detail

In this second line of survey, Mr Williamson holds an honourable place As a rule such systematisers lack the vision of pioneers Mr Williamson is no exception Nor has he the gift of style to help us over the crowded shingle of facts To take a specimen at random "Tyerman and Bennet say that Orion was known by name According to J R Foster the stars forming his Belt were called E whettoo mahoo Moerenhout says the stars of the constellation were called Fehone tarava, and guided their navigators at night The London missionaries say " (vol 1, p 125), but even the expert wants a pause in the midst of these enumerations

Lack of imagination leaves the treatment rather mechanical The geographical boundary is drawn by latitude and longitude rather than by a point of view By restricting himself to Central Polynesia (except for a few temptations to glance at islands just out of bounds) the author makes difficulties for himself Thus he is puzzled by the fact that in the Paumotuan myth of the separation of sky and earth the sky is female, not male as we have been brought up to expect This he has to explain as "an accidental mistake" (vol 1, p 28) Had he allowed himself a peep at Egypt he would have found the same myth with the sky as female What seems a mistake is really an important piece of evidence it proves there are two versions of the myth occurring side by side from the Near East to Polynesia But it is an axiom with this school that nothing ever travelled before our own culture except within restricted areas, such as Polynesia Any interchange of ideas outside those areas as between Polynesia and India, or Polynesia and America, is rigorously taboo

Equally mechanical is the classification, for example, into creation, sun, moon, stars, winds, and so on It is not with natural phenomena we are concerned, but with the minds that think about these phenomena, and there is not one department of the mind that deals with creation, another with the sun, another with the moon All these different phenomena may figure in the same system of thought, such as the creation cycle, which is one big system including myth and ritual of sun, moon, stars and many other things, on the other hand, the sun may figure in different systems, as in our creation myth and in our astronomy, two systems which some people manage to keep completely apart in their minds

For purposes of reference however, nothing can be more suitable than a mechanical classification such as the author adopts After all, no one has discovered a better arrangement of words in a dictionary than the purely mechanical one of following the alphabetical order It is as a work of reference that Mr Williamson's book has to be judged For new and fruitful points of view we shall look in vain The conclusions boil down to waves of migrations which are neither proved, nor worth proving, a mere variation on that most unfortunate theme, vol 2 of The History of Melanesian Society" It is sad that Rivers at his best should find no imitators, while Rivers at his worst is still taken seriously

The author could have laid the fault at the door of his authorities, but, like a good workman, he does not blame his tools Yet he might have done so with justice The literature on Polynesia is too much made up of scraps for the most part to give us a picture of any single culture as a whole It is only recently that we have come to realise that all these scraps are parts of recurrent patterns, and that it is those patterns that really matter (see, for example, 'Myth and Ritual , ed S H Hooke, Oxford, 1933) Mr Williamson could scarcely be expected to bring out those patterns since they are not in the materials he had at his disposal All he could do was to rescue for the student all those fragments which lie scattered in endless volumes, and leave the student to infer from the fragments the presence of patterns known elsewhere in their entirety That work Mr Williamson has done right well

As work of reference these volumes deserve nothing but praise The Tylorian school shines in such tasks With its best qualities the author is liberally endued It is easy to see the weak points of a school that is passing away, but when it has been dead for the lapse of a generation men begin to regret its virtues Mr Williamson almost makes one regret them before it has completely passed away, for in these days of competition for renown it is not common to find an equal degree of thoroughness, absolute honesty, self dedication to a laborious task, absence of demagogic arts, as we find in these pages The result is a complete and reliable survey of Polynesian mythology indexed in a manner which it is no exaggeration to describe as ideal The work will never have to be done again, because Mr Williamson has left nothing more to do

A M HOCART

Medical Genetics

The Chances of Morbid Inheritance Edited by Dr C P Blacker Pp xi+449+7 plates (London H K Lewis and Co, Ltd 1934) 15s net

THIS book, which is edited by the secretary of the Eugenics Society, sets out to help the practitioner to answer three questions which, as the editor states in his admirable preface, are often asked Ought I to get married ?" If I get married, ought I to have children ?" 'If I get married and have children, what are the chances of their inheriting my disease, or a disease which occurs in my family ?" Clearly only the third question can receive a scientific answer Many believers in negative eugenics will question the advice given elsewhere in the book that sufferers from certain diseases should be sterilised before marriage Such a course, among other things, virtually sterilises a healthy spouse Nor will the political views which are expressed by certain contributors meet with universal acceptance

The articles in the book are of very unequal value Some, such as Dr Campbell's on cardio vascular diseases, are not only excellent summaries of existing knowledge, but also contain new contributions to it The majority appear to be written in ignorance of certain essential facts disclosed by research on animals The most important of these is that genes causing abnormality often (probably in the majority of cases) do not manifest themselves in all individuals carrying them Thus Timofeeff Ressovsky found that in one genetically homogeneous line of *Drosophila funebris* carrying a certain pair of genes a particular abnormality showed in all members, while in another line it manifested itself in only 53 per cent of females and 80 per cent of males In certain crosses the gene which was generally nearly recessive, behaved as a dominant in about 5 per cent of heterozygotes This at once disposes of the statement in the chapter on 'Genetic Principles" that "if a condition appears several times from normal parents, then the conclusion that it is recessive is a safe one", and it renders unnecessary the hypothesis quoted by various authors (for example pp 48, 60, 421) as to the implication of several pairs of genes in certain family histories

Other authors appear to have overlooked much of the existing literature Thus the section on hereditary diseases of the eye contains no reference to Waardenburg's book on this subject, which is certainly the most complete in existence or to the Nettleship memorial volume of the 'Treasury of Human Inheritance" Still more unfortunate is the lack of reference to Cockayne's "Inherited Abnormalities of the Skin' The author of the chapter on skin diseases quotes three family histories of epiloia, and suggests that the condition is recessive Cockayne, after an analysis of twenty five families, comes to the opposite conclusion It is twice stated that infantile amaurotic idiocy is confined to Jews Slome listed eighteen cases in non-Jews

The article on skeletal defects is mainly concerned with embryology rather than genetics It devotes two pages to congenital club-foot in mice without mentioning Bonnevie's remarkable discovery that it is caused by the escape of fluid from a foramen in the embryonic myelencephalon which upsets the development of the limb rudiments No mention is made of such well known hereditary defects as osteopsathyrosis and multiple exostoses

If Mendelian studies are misinterpreted, the biometricians fare still worse Thus we read (p 396) that "Karl Pearson found in his series that tuberculous infection in a family tree bore vaguely the same ratio as the inheritance of other more easily recognizable characteristics' I take this to mean that the coefficient of correlation between parent and offspring for tuberculosis fell within the limits found for characters which are clearly inherited

When all criticisms are made, those chapters whose authors, instead of writing essays on heredity and environment devoted themselves to giving facts on which a prognosis can be based, are a valuable collection of data, enormously superior to that of Baur, Fischer, and Lenz, the only comparable work in English If a second edition is called for, we may hope that some of the mistakes will be corrected and the deficiencies made up, in which case the value of the book would be very greatly increased The index is imperfect

From the point of view of eugenics, serious inherited abnormalities may be classed as follows

(1) Dominants and sex linked recessives with approximately 100 per cent manifestation, for example, hæmophilia and blue sclerotics Here affected persons, or women who are certainly carriers, should not have children, but normal relatives can do so with comparative safety

(2) Dominants with incomplete manifestation, for example, cleft palate Here, unfortunately, unaffected persons may transmit the disease, and it is important to find means of detecting the gene where it is not clearly manifested, as Campbell and Warner did (pp 224, 272) in acholuric jaundice

(3) Autosomal recessives Here parents who have produced one abnormal child should produce no more, but it is not obvious that heterozygotes should abstain from marrying unrelated persons, as suggested on p 36 About 0 5 per cent of the population of Sweden carry a recessive gene for amaurotic idiocy, and probably few of us are devoid of undesirable recessive genes It is doubtful whether the knowledge that one such is carried should deter a healthy person from parenthood

(4) Conditions which may be due to several genes Here a family analysis is necessary But the chance of transmitting to the children a character which is not found in any of the parents or grandparents is usually small

A classification on these lines would not be difficult, and would greatly enhance the value of the book to practising physicians J B S H

Applications of Fluorescence Analysis

Fluorescence Analysis in Ultra-violet Light By J A Radley and Dr Julius Grant (Monographs on Applied Chemistry, Vol 7) Pp xi+219+14 plates (London Chapman and Hall, Ltd, 1933) 15s net

THIS book is designed to fill a gap in our technical literature, which up to now has yawned both deep and wide It is written by chemists for their *confrères*, but while the analyst and works chemist will appreciate every chapter, there are many others to whom it will prove valuable for guidance in empirical testing of their own special materials This will be so in the examination of textiles, minerals and gems, paints and varnishes, paper and various cellulose derivatives, museum specimens various foreign postage stamps and numerous other objects which are dealt with in nineteen classes, to each of which a separate chapter is devoted

Each section closes with a more or less extensive list of bibliographical references, which, the authors claim, amount in the aggregate to nearly 800 Each is numbered, and each number finds a place in the text where some indication of the contents of the paper is given, and all this is of permanent value Unfortunately, however, some of these undoubtedly enlightening passages are blurred by the statement being so confused as to leave the reader no alternative to resorting to the originals for instruction For example

> '*Glasses which Transmit Ultra-Violet Light* —W E S Turner and D Starkie[9] examined a number of commercial glasses covering the ranges 7000 to 2000 A and 2950 to 3150 A (which, how ever, is usually of therapeutic interest), and the following percentage transmissions were observed —Corex, 89 Sanalux, 73 Sun Ray, 62 Holvi, 61 Vita, 54 Helio, 52 Uviol, 46 Quartz Lite, 4
>
> Ordinary window glass[35] is taken as unity After use the various glasses showed a decrease in power of transmission varying from 13 per cent for Vita glass to 7 per cent for Sanalux" (p 23)
>
> '35" refers to a paper by H Valentin

The first 55 pages are devoted to "Theory and Technique of Fluorescence Analysis", which is arranged in five chapters dealing with theory, production of ultra-violet light, filters, measurement of intensity, and methods of examination Unfortunately, here also a similar laxity of expression prevails, thus on p 3

"(2) *The Ultra-Violet Region*, with which we are mainly concerned This is divided into the 'near' and 'far' ultra violet and extends from about 136 to 4000 A , the rays of the near ultra violet have the longest wave lengths and overlap with the violet rays of

(3) *The Solar or Visible Region*, the extreme wave length limits of which are about 0 0003 mm (near ultra violet) and 0 007 mm (infra red) This region constitutes what we call 'white light', which, of course, is the resultant effect on the eye of the colours of the visible spectrum '

and lower down on the same page

"*The Ultra Violet Region* —The position of this region is interesting It falls between the shortest rays visible to the human eye and the X ray region of longest wave length, about which little is known Generally speaking, therefore, ultra violet rays may be considered as intermediate in properties, such as penetration, between X rays and solar rays "

On p 2 we are told "the shorter the wave length the longer is the frequency"

A few typographical inconsistencies occur 0 007 for 0 0007 (p 3), A F Kitchen (p 93) and A F Kitchin (p 215) for A F Kitching T Brewis (plate No 2) for E T Brewis

The book is so useful in its scope that one must hope that a second edition will be called for, and so provide the authors with opportunity for improving the text, and at the same time rendering some of the more important sections a little more comprehensive

The book is uniform in style with others in the series edited by Dr E H Tripp, and is very well produced, especially the ten pages of luminograms on art paper at the end S JUDD LEWIS

History of Geography

(1) *A History of Exploration from the Earliest Times to the Present Day* By Brig General Sir Percy Sykes Pp xiv +374+25 plates (London George Routledge and Sons, Ltd , 1934) 25s net

(2) *The Making of Geography* By R E Dickinson and O J R Howarth Pp vi+264+5 plates (Oxford Clarendon Press , London Oxford University Press, 1933) 8s 6d net

EXPLORATION has provided the material out of which a science of geography has been created The gradual expansion of man's knowledge of the earth, obtained by voyages of discovery and journeys of travel, has been followed at every stage by a development of geography as a scientific subject The workers in the study and the map-room have slowly absorbed the results of exploration into the common stock of knowledge and welded them into a system It is therefore possible to write a history of two parallel developments on one hand, the history of exploration, and on the other, the history of geographical thought and ideas As the two subjects are closely related to one another, it is appropriate that two books dealing with these distinct aspects of geography should be discussed together

(1) Sir Percy Sykes is himself an explorer and he has been able to enrich his 'History of Exploration by personal knowledge of many of the regions described He followed in the track of Alexander the Great in 1894 He identified many sites in Persia that are mentioned by Arabian geographers He states that his chief ambition was 'to tread the Pamirs in the footstepp of Marco Polo and to shoot an *Ovis Poli* and on no expedition that I have made does the golden haze of reminiscence lie more brightly than that on which I successfully stalked these mighty rams in the remote upland valleys of the Roof of the World

As might be expected, the author pays special attention to the exploration of Asia, the continent in which most of his own journeys have been made, and includes an unusually detailed study of the unveiling of Arabia By comparison with his treatment of Asia, the author's accounts of the exploration of the Americas and of Australia are rather summary in character The book is well illustrated and includes a series of 36 maps, but it should be noted that 25 of these are reproduced directly from Mr J N L Baker's History of Geographical Discovery and Exploration" Sir Percy Sykes's book will not replace Mr Baker's standard work, but it should have a wide popular appeal and will serve as a useful introduction to the vast subject with which it deals

(2) Within the narrow compass of two hundred and sixty pages, Mr R E Dickinson and Dr O J R Howarth have endeavoured to describe the history of the development of geography as a subject, and they have been severely hampered by the limitations of space Dr Howarth has written the earlier chapters which deal with the history of geography before the great age of discovery , and this is probably the most satisfactory part of the book, although the achievements of medieval geographers are not fully appreciated

The task of writing the history of geography from the year 1500 up to the present day is a heavy one and perhaps the time is not yet ripe to make such a general survey Work such as that contained in Prof E G R Taylor's recent volumes on Tudor and early Stuart geography are the necessary preliminary before the history of geography as a whole can be written It is certainly too early to assess the place of contemporary British geographers in the development of the science, as is attempted in this book Mr Dickinson does not appreciate the relative importance of the geographers of the seventeenth century, and devotes a disproportionate amount of his space to some of the minor figures He barely mentions the great achievements of James Rennell who was justly described by the late Sir Clements Markham as the greatest geographer that Great Britain has yet produced The map which is supposed to show the progress of exploration is inexcusably inaccurate Mr Dickinson says that the goal of geography is the region and writes at some length on the development of the regional concept" in the nineteenth and twentieth centuries It will not be easy for regional geography to develop if, as Mr Dickinson suggests, much of the peripheral field of geography is to be abandoned to persons called "specialists in the other camp" (p 250) The reason that regional geography is so difficult and is so seldom successful is surely that it cannot be written without mastering the disciplines of several other camps

The second half of the book contains an unusually large number of errors in the spelling of names and similar mistakes The bibliography provided for the first half is very incomplete, and while the references are fuller in the later chapters of the book, many of them are difficult to verify The volume as a whole is not an improvement on the far less ambitious ' History of Geography" previously written by Dr Howarth in collaboration with the late Sir John Scott Keltie, a work which is still useful and deservedly popular E W G

Short Reviews

A Text Book of Chemistry By H A Wootton and C W R Hooker Pp xii+488 (Cambridge At the University Press 1933) 6s

THIS textbook bases the justification for its appearance on in particular, the fact that chemistry is a cultural subject and that many pupils will not continue a study of the subject after leaving school It may be said at once that the book is clearly and interestingly written, covering the range of the School Certificate examinations, and emphasises the applications of chemistry to everyday life and the paramount importance of the science in modern industry and manufactures

An outline of molecular theory is introduced immediately after the study of only oxygen, hydrogen and the gas laws then follow atomic theory and formulæ, and, separated by a chapter on water, equivalents, valency and equations Carbon, its oxides and the hydrocarbons are outlined before any of the common elements other than the halogens and nitrogen Although the scope of the book includes the theory of solution and molecular weights of dissolved substances, nothing is said about the periodic classification Experimental work is relegated to the second half of the book, where it is dealt with exclusively The net result is that it is difficult to find or co ordinate particular facts to which one may wish to refer The valuable interpretation of reactions afforded by the broad concepts of oxidation and reduction is largely lost since these concepts are not fully dealt with until after the non metals One would like, moreover, to see more prominence given in an up to date textbook to the generalisation of types of reaction The authors have however carried out their scheme with conviction and the student will have every reason to appreciate the importance of chemistry in all branches of life and industry There are eight excellent photographs as well as the usual line diagrams N M B

The Rise of the Celts By the late Henri Hubert Edited and brought up to date by Prof Marcel Mauss Raymond Lantier and Jean Marx Translated from the French by M R Dobie (The History of Civilization Series) Pp xxv+335+4 plates (London Kegan Paul and Co , Ltd , 1934) 16s net

THIS study of the Celts the result of many years' work, was still incomplete when the author died in 1927 It was completed in part and seen through the press by his friends with the assistance of lecture notes and a draft of the concluding chapter which will appear in a second volume M Hubert had an original outlook , and this was backed by a vast erudition upon which to base a synthetic view of the linguistic, archæological, anthropological and historical material, which it is necessary to master for an adequate discussion of the Celtic problem His analysis of the linguistic evidence, as it appears in this volume, where it is brought to bear upon the place of the Celtic people in relation to other Indo European peoples and on the relation of the Celtic people one to another, is of great value It deserves careful consideration, especially among those who hitherto have shown a tendency to pay too exclusive an attention to archæological evidence It was M Hubert's opinion that anthropology, that is, the study of physical characters in their racial aspect, can give little assistance, and it is a special merit of his study that he insists repeatedly on the distinction between a race', which the Celts were not, and 'a people, which they were, in the sense of a number of groups more or less closely related in a common culture and language In the use of linguistic evidence also he is careful to point out its limitations in arguments on races and peoples

The present volume gives only one half of the story, carrying it up to the Hallstatt period La Tène and the general characteristics of Celtic culture will be considered in the later volume

Geschichte der gegorenen Getränke Von Prof Dr A Maurizio Pp viii+262 (Berlin Paul Parey, 1933) 18 gold marks

Those who hope to glean from the pages of this book authoritative information on modern methods of the manufacture of alcoholic liquors or to learn something about recent theories of fermentation will be disappointed, for it is written mainly from the historical point of view It is, however a veritable encyclopædia of interesting facts relating to fermented beverages from the earliest times to the present day, and from the numerous references quoted, must have involved considerable industry and literary research Not only are the history and geographical distribution of the more common liquors, for example, beer and wine fully described, but similar details are given relating to lesser known beverages, such as mead, spruce beer, koumiss and various berry and herb wines There are also sections dealing with potato spirits and distillation, the latter being illustrated with interesting drawings of primitive distilling vessels

In addition to the account of the beverages themselves, the value of the book is enhanced by the inclusion of references to the basic materials—honey, sugar, herbs, grapes, malt, hops fruits—and to the different implements such as the wine press, used in the production of the various beverages The book concludes with a systematic catalogue of a large number of plants from which fermented beverages have been obtained

A J H G

A Text Book of Inorganic Chemistry By Prof Dr Fritz Ephraim English edition by Dr P C L Thorne Second edition revised and enlarged Pp xii+873 (London and Edinburgh Gurney and Jackson, 1934) 28*s* net

The success of the first English edition of this textbook, published in 1926, has justified the preparation of an up to date version Based upon the fourth German edition, the new issue contains also a good deal of supplementary matter supplied by Prof Ephraim and incorporated in the English text by Dr Thorne The general plan of the work, including the headings of sections and chapters, remains unaltered The revision has entailed an increase of about 8 per cent in the bulk of the book, and in the opinion of the reviewer a further expansion in future editions should be avoided Although by reason of its unusual plan it appears in some respects as predominantly a textbook of the non metals (see **Nature**, 119 7, Jan 1, 1927), the work has proved to be attractive and useful to students who have already secured a grounding in the subject, and the new edition will be welcomed

Sexual Regulations and Human Behaviour By Dr J D Unwin Pp xv+108 (London Williams and Norgate Ltd, 1933) 7*s* 6*d* net

Dr Unwin has made an inductive study of the effect of sexual repression and its relation to progress in human societies, of which this volume is a preliminary statement He has taken eighty societies under review, classifying them according to status as determined by certain characters He finds that the place of each in this grouping agrees with the degree to which pre nuptial sexual relations are subjected to repression, and in a final chapter he rapidly surveys the history of civilisation, showing that decadence has invariably followed the relaxation of sexual regulation While it is more than probable that Dr Unwin is right he has made out a case for further investigation rather than proved his contention No doubt the fuller treatment promised will strengthen the argument

Physical Mechanics an Intermediate Text for Students of the Physical Sciences By Prof R B Lindsay (University Physics Series) Pp x+436 (London Chapman and Hall, Ltd, 1933) 21*s* net

The vector method is followed in this book, and the treatment which usually ends with the mechanical properties of matter is continued to cover the kinetic theory of gases using the virial, the Bohr atom, a particle deflection electrical oscillations and wave mechanics The author s aim has been to make mechanics an introduction to advanced physics, in which he has succeeded admirably

An Introductory Course of Mechanics By E G Phillips Pp viii+255 (Cambridge At the University Press, 1933) 10*s* 6*d* net

The book opens with a short account of vector analysis, going as far as scalar multiplication and the differentiation of vectors The vector method of representation is kept to the fore throughout In this respect it has an advantage over the older books on mechanics, but the mathematics is of a higher order than that acquired by the average student at the time of beginning the study of mechanics However, the book will be of value to many students for the clearness of the treatment and the comprehensive set of examples

The John Murray Expedition to the Arabian Sea

By LIEUT COL R B SEYMOUR SEWELL C I E F R S

SINCE the previous report on the work of the John Murray Expedition (NATURE Jan 20 1934 p 86) H E M S *Mabahiss* has twice traversed the width of the Arabian Sea and in addition has cruised off the African coast between Mombasa and Zanzibar and to the east of Pemba Island

The *Mabahiss* sailed from Bombay on a traverse of the Arabian Sea to Mombasa on December 13 During the whole passage the weather was favourable and good progress was made observations being carried out at 12 stations As we approached the African coast we encountered a strong head current that kept us back somewhat so that we did not arrive in Mombasa until the morning of January 1 1934 We remained at Mombasa until the morning of January 9 and then sailed for Zanzibar in order to report to the Sultan and obtain permission to work off this region of the African coast Unfortunately during the whole of our stay in the Zanzibar area we experienced strong winds and there was a sufficiently heavy sea running to render the *Mabahiss* most uncomfortable while several members of the expedition contracted malaria

One very noticeable feature of the African coast in this region round Mombasa and Zanzibar is the extent to which coastal erosion is and has in the past been going on this is particularly evident on the west side of Pemba Island where most if not all of the bays and inlets are fringed with coral reefs on which small detached islets are to be seen still indicating the limits to which the original land extended in times past though now only the most resistant areas are left This erosion is particularly clearly seen in Chumbi Island about seven miles to the south of Zanzibar At the request of the authorities of the British Museum a visit was paid to this island in order to try to obtain evidence of the presence on the island of the giant robber crab *Birgus latro* the whole island consists of a raised coral rock' the upper surface of which has been weathered into holes and pinnacles by rain while the seaward margins have been eroded and undercut by wave action (Fig 1) The greater part of the island is covered with a profuse growth of a species of *Euphorbia* such as to render a thorough investigation impossible the crab however appeared to be well known to the resident lighthouse keepers and examples have been obtained on other islands in the group

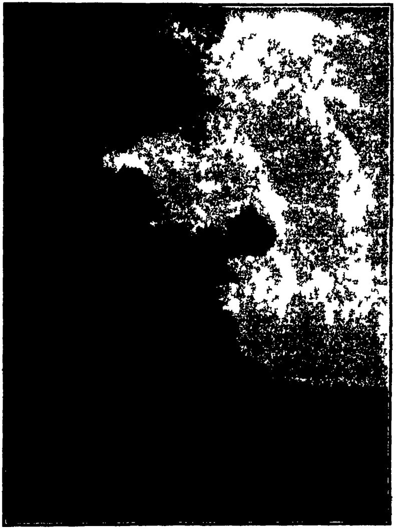

FIG 1 Chumbi Island showing coastal erosion

After leaving Zanzibar on our return passage across the Arabian Sea we encountered moderate winds and seas during the first few days but after that the weather again improved and after calling in at the Seychelles for extra coal we had a comfortable voyage past the Maldive Archipelago to Colombo though owing to a strong head current during the greater part of the journey our speed was considerably reduced During these three cruises we have carried out work at 45 stations, making a total of 135 stations in all up to date

TOPOGRAPHY and BOTTOM DEPOSITS

Lieut Commdr Farquharson, R N, has successfully managed to keep the echo sounder running practically continuously, though towards the end the apparatus required almost constant attention We have thus been able to map more than 5,000 miles of the sea floor along lines on which there were previously few, if any, soundings The late Prof J Schmidt, in his account of the voyage of the *Dana*, put forward the suggestion that there must be a deep ridge crossing the Arabian Sea from the south east towards the north west and connecting the Chagos Archipelago with Socotra and the entrance to the Gulf of Aden, we have now crossed this area twice and there can be no doubt that Schmidt was right On our voyage from Bombay to Mombasa in about long 59° E, a little to the west of where the Admiralty chart shows a sounding of 1,950 fathoms, we crossed a ridge on which the depth of water was only 1,650 fathoms (3,020 metres), though to the north-east the depth fell to 2,400 fathoms (4,392 metres) and to the south west it increased to as much as 2,910 fathoms (5,325 metres) On our return voyage from Zanzibar to Colombo we again crossed this ridge

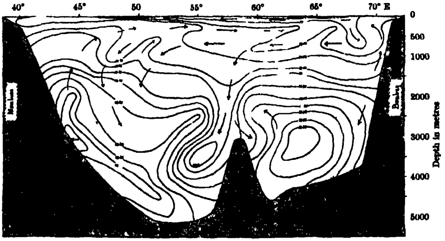

FIG 2 Halogen content of water between Bombay and Mombasa (Cl °/₀₀)

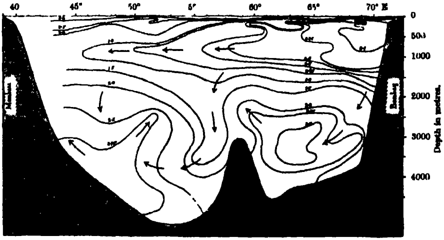

FIG 3 Oxygen content of water between Bombay and Mombasa

After leaving the Seychelles, we found that the bottom was very irregular In about lat 1° 20′ S, long 60° 30′ E we crossed a low ridge on which the depth of water shoaled to 1,570 fathoms (2,873 metres) To the east of this the depth of water increased to 2,600 fathoms (4,758 metres) and then the bottom rose again in a second ridge that lies between long 66° 00′ and 67° 30′ E, and over which there appears to be a general depth of from 1,600 to 1,200 fathoms (2,928 to 2,196 metres), though at two points depths as small as about 900 fathoms (1,737 metres) were obtained, with a deep gully having a depth of some 1,800 fathoms (3,294 metres) between them

Having crossed the first of these shallow areas and thinking that we were in the eastern basin, we carried out a complete station and were fortunate enough to bring up in the trawl a number of rock fragments, one of these has been examined by Mr J S Coates, mineralogist to the Ceylon Government, and he informs me that the rock consists of dolerite, a rock of the basaltic series that is frequently found associated with the Deccan Trap in India, the occurrence of this rock is of particular interest in view of the theory, held by many geologists, that a large section of basalt-covered Gondwanaland now lies submerged to the west of India Between this portion of the ridge and the western side of the Maldive archipelago the depth of water again increased to some 2,300 fathoms (4,209 metres)

It thus seems clear that there are two separate basins in the Arabian Sea one lying to the north east and the other to the south west of the diagonal ridge and it is of interest to note that a bottom sample obtained in the north eastern basin from a depth of 2 352 fathoms (4 305 metres) is of quite a different character from those obtained to the south west of the ridge it was a core 62 inches long of a comparatively soft reddish yellow ooze in which there appears to be very few Foraminifera and it seems probable that this is the type of deposit that Sir John Murray showed to lie between lat 5° and 12° N and long 62° and 72° E and classified by him as red clay though the depth is much less than would be expected for such a deposit

HYDROGRAPHIC OBSERVATIONS

During our voyage from Bombay to Mombasa and again during the return voyage from a point about lat 7° 30 S long 44° 10 E past the Seychelles to the entrance to Kardiva Channel in the Maldive Archipelago lines of hydrographic stations were run across the Arabian Sea The results obtained in the first of these traverses have now been tabulated and are given in Figs 2 and 3 In this section between Bombay and Mombasa there appear to be a series of currents and counter currents in the upper levels A study of the halogen content (Fig 2) shows that on the surface the water is streaming towards the south west under the influence of the north east monsoon wind while immediately beneath this upper stratum there is a counter current in the opposite direction at a depth of some 136 fathoms (250 metres) At a still deeper level approximately 400 fathoms (732 metres) the current is again moving towards the west but in long 68° E this mass of water becomes deflected downwards In this connexion it is interesting to note that in the region to the east of the Arabian Sea there are indications of a similar deep current at about the same depth and moving in the same direction*

As already mentioned the presence of a deep ridge separates the Arabian Sea into two basins and it is into the south west basin that the greater part of this descending mass of water is directed In each basin a mass of water of low salinity was detected that is almost certainly derived from the great antarctic bottom drift A study of the oxygen content of the water (Fig 3) at the different levels and at different stations gives an almost identical picture of the movement of the water masses the descending mass of tropic water with a low oxygen content being clearly distinguishable from the antarctic polar water in which the oxygen content is relatively high and in each basin there appears to be a vertical rotatory movement in progress the water on the eastern side passing downwards towards the bottom

Our work off Bombay has now made it possible to trace the movements of the water masses into and out of the Gulf of Oman (Fig 4) The main interest is the flow of water of a high halogen content (20 0 and above) out of the Persian Gulf towards the south east At the head of the Gulf of Oman this mass of water lies at a depth of 110–160 fathoms (200–300 metres) but as it is followed out of the Gulf it can be seen to sink gradually until off Bombay it is lying at a depth of 382 fathoms (700 metres) At a series of stations off Bombay we encountered the same or a very similar type of deposit to that found in the curious azoic region in the Gulf of Oman referred to in the earlier report of the Expedition The deposit from a depth of 156 fathoms was similarly though to a rather less extent than off the Arabian coast impregnated with sulphuretted hydrogen and here too the result of three trawls yielded remarkably little in the way of animal life

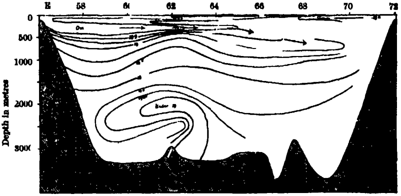

FIG 4 Halogen content of water in the Gulf of Oman (Cl)

BIOLOGY

The region of the African coast under investigation proved to possess a very rich fauna and good catches were made at a number of stations in water the depth of which ranged from 100 to 500 fathoms (183 to 915 metres) In shallower depths our nets were badly torn by coral while in depths greater than 660 fathoms (1 200 metres) there seemed to be evidence of a distinct falling off in the quantity of life at the bottom Sometimes large catches were made thus at one station at a depth of 802 metres an hour s haul with the Agassiz trawl resulted in our securing a hundred examples of a species of *Phormosoma* probably *P indicum* and masses of a species of *Virgularia* At another station we secured some 114 examples of fish belonging to about twenty species and nearly as many genera , together with some 58 asteroids and about 700 examples of an ophiuroid

---

* Sewell, R B Seymour 1932, Geographic and Oceanographic Research in Indian Waters Part VI Temperature and Salinity of the deeper waters of the Bay of Bengal and Andaman Sea *Mem Asiatic Soc Bengal* 9 No 6. See pp 377–378

The general richness of the fauna provided a very marked contrast to the comparatively barren region round the Arabian coast and the azoic area of the Gulf of Oman Until the collections have been worked out, it is impossible to give any details of the fauna of this African region, but the general impression created is that this region round Mombasa and Zanzibar has a fauna much more nearly allied with the fauna of the southern coast of the Gulf of Aden than with that of the northern coast of the Gulf

Chemistry and Chemists in Spain

AT the tenth meeting of the Union Internationale de Chimie held at Liège in 1930 apart from formal business, an adequate amount of time was devoted to consideration of problems connected with the constitution and properties of the simple and complex carbohydrates Comprehensive papers previously circulated by recognised authorities prepared the way for useful discussions, and only in one or two cases was discussion rendered impossible by the tedious reading by authors of long manuscripts which either had been or should have been circulated previously In spite of one or two drawbacks, the Liège meeting indicated how scientifically useful such international meetings may be when suitably organised

When the invitation to hold the eleventh meeting of the Union in Madrid was accepted it was decided by leading Spanish chemists to revive the pre War International Congress of Chemistry at the same time, with the object of consolidating the scientific side of the meeting The last meeting of the International Congress was held in Washington in 1912 and the meeting, postponed from 1932 to 1934, held in Madrid (April 5–11) constituted the Ninth International Congress Some confusion may have arisen even among those attending that Congress and the eleventh meeting of the Union Internationale

In spite of all the difficulties which have attended their work of organisation during the last two years, our Spanish colleagues have entertained their guests with lavish hospitality, both scientific and otherwise The Congress and the meeting of the Union were opened in the ultra-modern Salle Capitol in the presence of the president of the Spanish Republic, who made what appeared to be an impressive speech in Spanish after the reading in Spanish by Prof Fernandez of an account (previously circulated) of the developments in chemistry since the Eighth Congress There were about 1,200 on the list of ordinary members of the Congress This list included also the ladies who were kept busy enjoying the artistic and other treasures of Madrid, while the chemists were supposed to be busy discussing some of the 245 scientific communications, attending the four special lectures such as that of Prof G N Lewis on "The Different Kinds of Water" and listening to the twenty special papers such as those given by Profs P Walden ('Anomale Elektrolyte in nichtwässerigen Lösungen"), G Barger ("On the Alkaloids of the *Iso*chinolin Group '), R Robinson (Molecular Architecture of Plant Products"), R H Kruyt ('The Modern Development of Colloid Chemistry ') P Karrer (Untersuchungen uber Carotinoide und Vitamine") and Miss Jordan Lloyd (The Chemistry of the Tanning Process with Special Reference to Vegetable and Chrome Tanning) the only lady chemist taking a leading part in the last two groups of special papers Nearly all the communications to the Congress were circulated beforehand and intended to be the basis of discussion

This huge scientific programme was interspersed with receptions by the president of the Republic at the National Palace and by the Mayor of Madrid at the Town Hall, visits to Toledo and Segovia and artistic entertainments terminating with a well attended banquet One heard also of several official or semi official lunches and dinners and of private excursions before the dispersal of the delegates to the many places of interest in the south of Spain and even to Morocco Everywhere the members of the Congress were most kindly and graciously received and, apart from the somewhat adverse climatic conditions in Madrid, there was no sign anywhere of discomfort, alarm or even disquietude The graciousness of our hosts was shown in a more permanent fashion by the conferring of honorary doctorates of the University of Madrid on seven delegates, among whom are Profs H E Armstrong and R Robinson, the election of ten foreign members of the Spanish Academy of Exact Sciences, among whom is Prof G Barger and, finally, the conferring of the new Order of the Spanish Republic on another eight delegates, among whom is Prof E Bulmann, president of the Union Internationale

The permanent result of the Ninth International Congress is not easy to forecast Many hope that its scientific proceedings will not be buried in a separate huge volume, but will find their way into more accessible journals devoted to the publication of contributions to chemical knowledge

The meeting of the Union Internationale seemed to be overshadowed and was confined to two sittings of the Council and one of the Bureau, apart from those of several of the committees In formal business, Prof N Parravano (Rome) was elected to succeed Prof Bulmann in the presidency and the new members of the Bureau are Profs M Bodenstein (Berlin), E Bartow (Iowa), F Fichter (Basle), K Matsubara (Tokyo) and W Swietoslawski (Warsaw) The decision to accept the invitation to hold the twelfth meeting of the Union in Switzerland in 1936 was confirmed

The chief subject of discussion by the Council concerned future arrangements for organisation concerning chemical nomenclature The existence of separate committees for organic and biochemical nomenclature has for some years been regarded as unfortunate by many chemists in different countries, and the British Federal Council for Chemistry has been active in trying to have the two committees combined The tone of the discussion was somewhat heated, and 'Anglo Saxon' opposition to the existing committee on biochemical nomenclature was referred to in terms which created an atmosphere scarcely suitable for critical consideration of the best policy regarding a question of fundamental importance in chemistry

The following proposals by Prof F Swartz were submitted "In conformity with the decision of the Union the Committees on nomenclature are dissolved The Council decides to constitute three new committees on nomenclature, one for inorganic chemistry, one for organic chemistry and one for biochemistry These committees are asked to present a scheme of organisation of the future work of the committees on nomenclature to the Union before 31 December, 1935 Their presidents will assure the co ordination of the work of these committees The members of the committees will be chosen as far as possible from among the members of the former committees These proposals were voted on according to countries adhering to the Union and passed by 29 to 28 votes That there should be five members of each commission was again voted on in the same manner and passed by 31 to 27 votes It was finally left to the Bureau to choose the members of the committee

It may be questioned whether decisions of such a nature should be determined by countries having a number of votes based on their population and not by individual votes of representative chemists keenly interested in the matter, but an important advance will be made if, by 1936, the relative positions of organic chemistry and biochemistry on the question of nomenclature common to both are satisfactorily defined C S Gibson

Aberdeen Meeting of the British Association

THE preliminary programme of the meeting of the British Association to be held at Aberdeen on September 5–12 has now been issued In certain respects a university city affords the best and most appropriate setting for a meeting of the Association, and Scottish meetings are anticipated with pleasure, for their standard of organisation has always been high, and they have always attracted a notable measure of public interest

In Aberdeen, the accommodation for the sessions will be very convenient, for eight of the sections will be housed in Marischal College, and of the rest, four will find rooms within a quarter of a mile of the College Only the Section of Botany will sacrifice nearness to the centre to the convenience of meeting in the appropriate department of the University, with its fine gardens, at St Machar The Reception Room will be in the Music Hall, a building of special historical interest to the Association, for it was opened in 1859, and the first ceremony which took place in it was the inaugural meeting of the Association in that year, when the Prince Consort occupied the chair He conveyed a message from Queen Victoria to the Association, and delivered an address which is a pronouncement of no little interest in the history of science His own sympathetic and well-informed attitude toward science is well known, and is clearly defined in this address, and no less clearly is indicated the general position of science in the life of the community at that time

This point is apposite to the present programme, since particular contacts between science and the life of the community will be more prominent as subjects of discussion at Aberdeen than they are usually Such topics are of course, always to be found in Association programmes, but in recent years, and especially last year at Leicester, it has become clear that lay members and those who follow the proceedings of the meeting in the Press wish to hear more of them It seems natural and proper that this should be so, and it is obviously within the stated objects of the Association that such a demand ought to be met It is announced in the preliminary programme that 'several Sections are including in their programmes papers or discussions within the scope of the resolution forwarded by General Committee to Council at the Leicester Meeting last year, on the relation between the advance of science and social progress', and a number of appropriate subjects are already announced If from some of these there should emerge at Aberdeen applications for the appointment of committees to pursue investigations this will mean that the Association's machinery is being used for the advancement of science in specific directions of public importance There will be nothing new in this The Association's record affords sufficient evidence for that statement But the giving of "a more systematic direction" to scientific inquiry was one of the charges laid upon the Association by its founders, and here, surely, is a systematic direction which has been rightly pointed out and will be rightly followed

Sir James Jeans, who has succeeded the late Sir William Hardy as president of the Association, announces the title of his address as The New World Picture of Modern Physics" It is stated that one of the usual evening discourses will be given as a Sir William Hardy memorial lecture, and will deal with the preservation of meat, fish and fruit, a subject peculiarly appropriate to Aberdeen, where the work of the Torry Research Station is very well known The name of the lecturer is not yet announced The other evening discourse will be given by Prof W L Bragg on "The Exploration of the Mineral World by X Rays" Reverting to the subject of science and the community, the programme states tentatively that an evening symposium on the general relations of these may be arranged The sectional programmes, so far as can be judged from the short summaries furnished in this preliminary announcement, are certainly no less wide ranging than usual An ambitious series of excursions is under consideration and inasmuch as the occasion of a meeting in a centre commanding this part of Scotland must needs be rare, the opportunity should be taken

This programme is accompanied by a circular addressed to those who are not life-members of the Association, which in effect asks them to pay regular subscriptions to the Association by signing a banker's order form, whether they attend the meetings regularly or not The hope is to assure a more stable income for the Association, and thus 'alleviate the difficulty of allocating grants in aid of important research", for which the applications habitually exceed the sums available The Association's support of research, and the preparation of reports on the state of science", which began in 1834 and has never since been intermitted, sufficiently justifies this appeal

Obituary

DR WALTER ROSENHAIN, F R S

IT is a grief and a shock to me on returning from a holiday abroad to read of the death of Walter Rosenhain I have had many pupils but none more gifted with the imaginative insight of the discoverer more discriminating in criticism, or more skilful in the technique of the experimentalist He came to me, in the late nineties with a research scholarship from the University of Melbourne, when I was professor of mechanism at Cambridge, and asked me to suggest a piece of research which he might undertake in my laboratory At that time Roberts Austen, Arnold, J E Stead Osmond and others were applying to metallurgical analysis the microscopic methods which had been initiated by Sorby in his earlier study of metals and it was beginning to be recognised, somewhat vaguely, that the irregular grains which a polished metal revealed in the microscope were crystals the boundaries of which had interfered with one another in the process of crystal growth I suggested to Rosenhain that this opened up a good field, and that it would be interesting to see what happened when a plastic metal was overstrained The supposed crystal grains must alter their form, but how ?

Rosenhain had already begun in Melbourne a research on steam jets which he was anxious to finish first, and we arranged that as soon as he had completed that he should take up the metallurgical inquiry This was done, and I recall very vividly how, after he had acquired some skill in polishing and etching metallic surfaces so as to bring out the granular structure, we put a plastic strip one day under the microscope, fixed in a straining stage so that it could be stretched while one watched the surface of the grains As the straining proceeded we saw lines appear, sharply defined parallel lines which were black in the reflected illumination, becoming more numerous the more the specimen was stretched, and tending to develop criss cross patterns The laboratory was closing for the day, so we went our several ways, each brooding on what these curious lines might mean That evening I saw the interpretation the lines must mean finite slips, taking place on parallel layers within the grain Consequently the grains *were* definite crystals, and remained crystals after the deformation they gave way, when the straining passed the elastic limit, by the sliding of bands or layers on a group of parallel planes much as a pack of cards might be sheared Slips of this kind in three directions inclined to one another within each grain would allow the grain to assume a new form consistent with the plastic straining of the piece as a whole Next day we met again, and I found that Rosenhain had, quite independently, come to the same conclusion That was the discovery of 'slip bands' which we published jointly in a preliminary notice to the Royal Society in March 1899 (*Proceedings*, vol 65), and later (along with much more) in the Bakerian Lecture of that year (*Phil Trans* , A, vol 193, p 353)

We pursued the research hotly together It was a happy as well as a fruitful association To work with such a pupil was, for the professor, a rare delight and a constant stimulus It turned out that metallurgy did offer to Rosenhain the most congenial field that could have been chosen Looking back now, I feel a natural pride in having guided him to it Afterwards, when the days of pupillage were past, I had the continued pleasure of watching him go on from strength to strength and receive growing recognition, of visiting him from time to time at the National Physical Laboratory where he made a position worthy of his powers, and of listening to his admirably lucid expositions, public or private An old man, such as I am, must reckon with the loss of his contemporaries, but it was far too early for us to lose Walter Rosenhain J A EWING

DR WALTER ROSENHAIN, whose death at the early age of fifty-eight years occurred on March 17 last, had a world-wide reputation as a metallurgist, and for more than thirty years had taken a leading part in the development of the new science of metallography Born in Melbourne, Australia, on August 24, 1875, he graduated in engineering at the University of Melbourne, in 1897 and proceeded to Cambridge as the holder of an 1851 Exhibition Scholarship Here he worked with Prof (now Sir Alfred) Ewing, and began to use the microscope in the study of metals In 1899 appeared a memorable joint paper, describing in detail the mechanism of deformation of metals by slip, which has formed the basis of all later work on the subject

Rosenhain then entered the works of Messrs Chance Bros , and for about six years was engaged in work on optical glass, although continuing his studies of metals His well known textbook of Glass Manufacture ' was first published in 1908 a second edition being called for in 1919 In 1906 he became superintendent of the Department of Metallurgy at the National Physical Laboratory succeeding Dr (now Sir Harold) Carpenter This post he held for twenty five years, during which time the staff increased from four to about seventy, whilst the long series of important communications which issued from the Department under his direction was evidence of his success in guiding and inspiring his collaborators, his loyalty towards whom was unfailing This work covered a wide range His own interests lay chiefly in the field of what he preferred to call "Physical Metallurgy' (the title of his textbook published in 1914)—the study of the properties of metals and alloys in relation to their structure

On the practical side, perhaps the most striking achievement during this period was the work on the light alloys of aluminium, largely conducted in view of the requirements of the War, and carried out under conditions of urgency The results were of great importance for the progress of air craft construction, and the Eleventh Report of the Alloys Research Committee, in which they are recorded, marks an epoch in the development of the alloys of aluminium

This Committee, established by the Institution of Mechanical Engineers, was later transformed into the Alloys of Iron Research Committee, and a series of studies of the binary alloys of iron with other elements was begun, special attention being given to the production of the elements used in the highest state of purity Such work involved the introduction of new methods of research at high temperatures, and the improvements of technique have done much to smooth the path of future investigators

On the theoretical side, Rosenhain was particularly associated with conceptions regarding the behaviour of metals on deformation and when undergoing thermal treatment The hypothesis of an 'amorphous' phase, existing between the crystal grains of a cast metal and in the deformed portions of crystalline metals, was applied by him with the greatest ingenuity to explain creep and other effects depending on time and temperature

As a lecturer and debater on metallurgical subjects Rosenhain was unrivalled He could give an account of experimental work or expound a theory in simple language, with a fluency which never hindered the logical arrangement of the steps in his argument, whilst his quickness of thought and skill in debate gave interest to his frequent interventions in metallurgical discussions He was often involved in controversy, and could be scathing in his criticisms, but maintained an even good humour under all conditions In 1931 he retired from his post at the National Physical Laboratory, and until his death carried on a successful practice as a consulting metallurgist, without slackening his scientific activities

Rosenhain was elected a fellow of the Royal Society in 1913 He was active in the formation of the Institute of Metals, of which he was president in 1928–30, also delivering the May Lecture in 1923 He received the Carnegie Medal of the Iron and Steel Institute in 1906 for an early research on the strength of steel at high temperatures, a subject which he pursued with great success at the National Physical Laboratory, and was awarded the Bessemer Medal in 1930 His fluency in French and German made him a valuable link with foreign metallurgical bodies, and he took a special interest in the International Association for Testing Materials of which he became president, and would have presided at the congress planned to take place in London in 1935 On such bodies, and on committees of the British Standards Institution, his clear ideas as to what should be done and his courage in maintaining his opinion gave great weight to his collaboration

Dr Rosenhain is survived by his wife, a sister of the late General Sir John Monash of Melbourne, and by two daughters

---

PROF S H VINES, F R S

WITH the death of Sidney Howard Vines at the age of eighty four years, another leading botanist of the older generation has passed away Though he had lived in retirement at Exmouth since 1919, his help and advice were not infrequently sought, and he still took an active interest in botanical matters

Born in London in 1849 and educated at a private school, Vines afterwards entered Guy's Hospital, but gaining a scholarship to Cambridge he went up to Christ's College in 1872 Being somewhat more mature than the average undergraduate, and having some preliminary training in science, he distinguished himself already in his undergraduate years and as such was offered in 1874 the appointment of demonstrator in Huxley's course of general biology at South Kensington As he says in the Huxley Centenary number of NATURE (1925), Huxley's lectures were a revelation to him, so lucid, so well proportioned, so convincingly expressed. Altogether it was a memorable and an invaluable experience in the art of teaching. In the following two years the botanical portion of Huxley's general biology course was given by Thiselton Dyer, and in both courses Vines acted as demonstrator.

In 1875 Vines graduated with first class honours in botany and in the following year was elected fellow and lecturer of his College. By way of equipping himself still further for his future work he decided to visit some well known German laboratory and having been stimulated while at Cambridge by the teaching of Sir Michael Foster, desired to devote himself to the physiological side of botany. He was anxious therefore to study under Julius Sachs, then at the zenith of his activity and fame as a plant physiologist, and having obtained leave of absence for the Easter term of 1877, he spent this time at Würzburg under the stimulating direction of Sachs, taking up the study of the growth of plants in relation to light. In an account he published some years ago of his studies abroad he tells us that Sachs's lectures were "delivered with such lucidity and force that familiar things became instinct with new life". He formed a lasting friendship with Sachs and was both the instigator of, and a generous donor to, the fund which was raised a few years ago to acquire the portrait of Sachs for the Linnean Society.

On his return to England, Vines started a botanical laboratory in Cambridge through the kindness of Sir Michael Foster, who lent him a room in the newly erected Physiology Laboratory. Later, when he was appointed reader in botany at Cambridge, more permanent accommodation was provided in the ground floor of the Botany Department. But though now provided with a laboratory, then an innovation, Vines found that he could not do justice to the practical side of the various branches of botany and felt particularly, as he tells us, the need of acquaintance with methods for the study of fungi. He consequently decided to visit the laboratory of De Bary, the eminent mycologist. In 1880 he obtained two terms' leave of absence and spent the beginning of this time with De Bary, but the greater part with Sachs at Würzburg. Thus, in those early days when there were no facilities for practical work in botany in Great Britain, Vines obtained the necessary training for the development of practical botany on his return. Other leading botanists of those days like D. H. Scott, Marshall Ward and F. O. Bower did the same. They sought and found in Germany what was at the time unobtainable in England.

In 1883, Vines was appointed reader in botany in Cambridge, and when the Sherardian chair in Oxford became vacant in 1888, he was appointed successor to Prof. Bayley Balfour. The chair of botany at Oxford had been held by a number of distinguished men and botany had received no small encouragement at the hands of the University. Still, Vines considered it necessary in his inaugural lecture to put in a further plea for botany as an academic subject, actuated in part by a desire to meet the severe and unsympathetic attitude of Ruskin, who a few years previously had criticised "the vulgar and ugly mysteries of the so-called science of botany". As Vines said, he felt these strictures all the more keenly because of his deep sense of indebtedness to Ruskin "for much that adds charm and interest to life".

For thirty-one years, until his retirement in 1919, Vines held the professorship with distinction, witnessing the growth in importance of botany in the University curriculum and the addition of the cognate school of forestry, the organisation of which entailed considerable addition to his duties. His interest in the practical side of botany led to the publication, in conjunction with Prof. Bower, of a most useful "Course of Practical Instruction in Botany" in 1888. He adapted a leading German textbook of botany by Prof. Prantl for the use of English students (1895). In 1886 he had already published his excellent course of "Lectures on the Physiology of Plants", which was for long the standard English book on the subject.

Though primarily a physiologist, Vines was interested in the valuable herbarium of the University of Oxford and with the help of Dr. Claridge Druce published an account of "The Dillenian Herbaria" (1907) and later of "The Morisonian Herbarium" (1914), both full of interesting historical and biographical matter. For many years Vines was one of the editors of the *Annals of Botany* to which he contributed numerous papers on physiological subjects. The earlier of these dealt with more general problems such as root pressure and transpiration, the mechanism of the stomata, epinasty and hyponasty; the later ones were concerned with proteolytic enzymes, and this latter series taken together give an excellent account of the occurrence and function of the proteases in the vegetable kingdom.

Vines always preserved, however, a general interest in botany, as is shown by his article on "Plant Morphology" in the eleventh edition of the "Encyclopædia Brittanica", which is still well worth reading. He naturally refers in it to Sachs's theory, that morphological differences are the expression of differences in material composition, and though this theory had to be considerably modified, he held that the discovery by Sachs that a small quantity of a substance can affect the development of an entire organ, foreshadowed the subsequent discovery of growth-promoting substances or hormones.

Vines's eminence in botany was recognised by his election to the Royal Society in 1885, while still reader at Cambridge. He joined the Linnean Society in 1878 and acted as president in 1900–4. A good portrait of him by the Hon. John Collier hangs in the rooms of the Linnean Society.

Both when in Oxford and afterwards during his retirement at Exmouth, Vines took a keen interest in his garden, devoting himself with skill and enjoyment to the cultivation of plants Unfortunately, his health latterly left much to be desired, and he passed away on April 4

The charm of Vines's personality gained for him a large number of warm friends among his colleagues, and botanists of a younger generation will always be grateful to him for the kindliness with which he treated them and the ever ready help he so willingly extended to them

F E W

DR MARIA A VAN HERWERDEN

THE cause of biological sciences as linked to the evolution of man has sustained a severe blow in the death of Dr Maria Anna Van Herwerden on January 26 at Utrecht, where she had long taught in the University in the Department of Embryology, Cytology and Genetics From its early days she was a leader in the International Federation of Eugenic Organisations, as well as being one of the first supporters of the International Union for the Scientific Study of Population Problems, and had a wide circle of friends in Great Britain In Holland her foresight and untiring work contributed much to building up the Central Committee of societies working in the field of human genetics, which resulted in the foundation last year of the Netherlands Institute for Research in Human Genetics and Race biology *Mensch en Maatschappij*, No 2, says of her "She was a modest woman, never putting herself forward, without self seeking, simply serving the cause for which she stood, with great enthusiasm and devotion her strong will and sense of duty found her always ready with help and advice Her counsels always carried the greatest weight, founded as they were on wide knowledge illumined by clear insight and judgment and presented sympathetically as the outcome of a benevolent spirit in clear cut elegant form the Sciences of Human Genetics and Eugenics have lost their most outstanding exponent in our country in the passing of this courageous and talented woman "

WE regret to announce the following deaths

Prof R Chodat, since 1889 professor of botany in the University of Geneva, rector of the University in 1908–10 and first president, in 1901, of the Association Internationale des Botanistes, aged sixty nine years

Sir George Duckworth, C B, secretary of the Royal Commission on Historical Monuments (England) in 1908–33 on April 27, aged sixty six years

Prof W H Welch, emeritus professor of the history of medicine and emeritus director of the School of Hygiene and Public Health at Johns Hopkins University, Baltimore, on April 30, aged eighty four years

Mr W G Whiffen, manufacturer of drugs and fine chemicals, one of the original fellows of the Institute of Chemistry, on April 28, aged eighty-two years.

News and Views

Prof C V Boys, F R S

PROF C V BOYS, who is delivering the Guthrie Lecture of the Physical Society on May 4, is the doyen of physicists of what may be called the classical age of experimental physics In one of his earliest researches he succeeded in photographing rifle bullets in flight To Boys we owe the production of quartz fibres, those almost invisible threads having remarkable elastic properties which are indispensable in many galvanometers, etc Boys produced them very simply by shooting an arrow, to which a short piece of partially fused quartz was attached, across the room, the unfused part being held behind Employing these fibres, Boys was able to eliminate most of the errors of the Cavendish experiment and succeeded in weighing the earth with an accuracy neither before nor since surpassed His experiments with bubbles set out in his fascinating book Soap Bubbles and the Forces that mould them' are still an unfailing source of interest to old and young Telescope design, sun dials and a camera for following a lightning flash throughout its course, have also occupied his attention With the passage of the Gas Regulation Act, 1920, the design and construction of a calorimeter for measuring and recording the calorific value of towns' gas became a matter of urgency Boys had already invented a gas calorimeter, but the step from a snap test device to a recording instrument was a long one. Boys succeeded, however in constructing such a recorder, and it has been in continuous use recording the calorific value of gas supplied in certain parts of the country The instrument incorporates a very large number of most ingenious but typically Boysian' devices To mention but one, a thinking machine' automatically corrects the volume of gas burnt in the calorimeter to normal temperature and pressure and continually records the correcting factor

Research and Development Lectures

WITH the object of promoting attention to the importance of research—both purely scientific and technical—and the utilisation of its results in the service of mankind, the British Science Guild arranged last year for the delivery of a Research and Development Lecture by Sir Harold Carpenter on "Metals in Industry" It was originally intended that one such lecture should be delivered annually, but Lord Melchett, president of the Guild, has given the scheme much wider national significance by arranging several discourses in which the broad trend of scientific development of subjects will be illustrated by experiments and practical demonstrations By kind permission of the managers, the lectures will be delivered in the historic lecture theatre of the Royal Institution. The first of the lectures, at which the Prime Minister will preside, is to be delivered as we go to press, on Wednesday, May 2, by Sir William Bragg on 'The Development of the Principles of Refrigeration", and the second, on Wednesday, May 30, by Lord Rutherford on 'Helium and other Rare Gases". It is hoped to arrange for two further lectures of the same type to be delivered in the autumn.

The particular aim of these Research and Development Lectures is to enable legislators, administrators and other responsible leaders to make contact with outstanding achievements of practical science. There is no lack of interest in scientific work and thought among most of these representatives of progressive national life, but few lectures have been specially designed to appeal to them. Lord Melchett's action in providing for such lectures has, however, been warmly supported by men of science and laymen alike and we congratulate him and the British Science Guild upon the success of a notable national endeavour.

Progress of Automobile Engineering

For the James Forrest Lecture which he delivered at the Institution of Civil Engineers on May 1, Sir Henry Fowler took as his subject "The Progress of Automobile Engineering". After a tribute to Forrest, whom he had known when a student, Sir Henry said that to-day the automobile industry is the fifth in point of size in Great Britain, while in the United States in 1928 the industry used no less than 6,000,000 tons of steel. The industry is also one of the greatest consumers of rubber, cotton and light alloys. The first self-propelled vehicle was that built in 1769 by Cugnot, and this was followed by those of Murdoch and Trevithick. Between 1823 and 1840, many patents were taken out for steam carriages, and the same period saw the experiments of Hancock, Gurney, Dance and others. Of the details then invented, the chain drive and differential gear of Hills and the steering gear of Gibbs has survived. Prohibitive tolls, vested interests and the railways, however, led to the abandonment of these early experiments and then came the 'Red Flag" Act of 1865, with restrictions which were not removed until 1896. But the matter was taken further by the work of Otto in 1876 and Daimler in 1883, the latter giving us a power unit which has changed our lives, much as the railway did a century ago. The outstanding personality of the early period of automobile development was Levassor, whose arrangement of the various parts of a motor car has been followed generally. Progress from about 1895 until 1901 can be traced from the records of trials, one of the most important of these being that held by the Royal Automobile Club in 1900, when eighty-three cars, most of foreign origin, started on a 1,000 miles run.

A great part of the lecture was devoted to the details of the subject—materials, tyres, engines, gears, clutches, springs, brakes, etc. Improvements in materials have been continuous and have led to the introduction of various alloy steels and alloys of aluminium such as duralumin, "Y" alloy and that known as "R R". The investigation of these light alloys has led to an almost new technique. Recently, success has been achieved with a lead bronze alloy for bearings. As for the tyres, pneumatic tyres were first conceived by Thomson in 1846, and developed by Dunlop in 1888 and first made for motors by Michelin and Co. In 1906 it was said that tyres cost "perhaps five or six times what the fuel cost per mile run", but the cost to-day is probably less than one quarter of the cost of fuel. In engine design the greatest advance of recent times has been the development of engines for using heavy oil. Compared with the petrol engine, the compression ignition oil engine is slightly heavier, but has a higher efficiency and greater turning moment at low speeds. The problem of transmission, perhaps, is given more consideration to-day than any other. Many alternatives to the 'crash' gear have been tried, and not only in automobile but also in other classes of engineering, the matter has proved one of the most difficult problems in mechanics to be solved at a low cost and with high efficiency. In connexion with this part of his subject, Sir Henry described the Wilson gear, the Austin Hayes gear, the Leyland hydraulic converter, the so-called fluid fly-wheel and the automatic clutch manufactured under the Newton patents. He also touched upon types of brakes, and methods of suspension, and in his conclusion recalled the remark of a friend that in early days cars were extremely simple and extremely unreliable, whereas at the present time they are extremely complicated, but leave nothing to be desired so far as reliability is concerned.

Spicer-Dufay Colour Film

Since 1926 the Spicer-Dufay process of colour photography has been the object of very intensive research and a demonstration of colour films made by this process was given at a Royal Society soirée in 1931 (see Nature, May 30, 1931, p. 821). It is stated that the new product will shortly be marketed for 16 mm. cinematography, and later it is intended to supply also roll films for ordinary cameras and standard 35 mm. cinematograph film. The new film consists of a transparent base on which is first coated a three-colour mosaic of regular pattern; in intimate contact with the colour mosaic screen is a very thin waterproof layer and above this is a highly sensitive panchromatic photographic emulsion. Exposure is made through the film base and colour mosaic. A positive image is formed by reversal. In principle, the process is thus similar to many which have long been operated with great success for still photography in colour.

The application of this general principle to cinematography has necessitated a very thorough study of every detail of the process. For example, in still photography it has been found quite satisfactory to use an irregular colour mosaic, the primary coloured elements being distributed in an entirely haphazard manner, it is reported that when this type of mosaic is used for cinematography, the superimposition of successive pictures built up of colour elements arranged in entirely different ways gives rise to a very unpleasant effect known as 'boiling', every part of the picture on the screen appearing to be in rapid internal movement With the Dufay regular mosaic this trouble does not occur The success of a process for colour cinematography depends on a variety of factors besides its power to yield pleasing coloured pictures Two very important desiderata are that films should be capable of projection with normal projectors as used for ordinary black and white pictures, and they must be capable of yielding coloured duplicates by a process of automatic printing In respect of the first of these requirements, the Spicer Dufay process has already achieved its object and the luminosity of the projected pictures is at least adequate, while a method of duplicating by machine printing is now available The process is therefore one in which technical achievement is already very high

Royal Institution and Davy Faraday Laboratory

THE annual meeting of the Royal Institution was held on Tuesday, May 1, under the chairmanship of the treasurer, Sir Robert Robertson The Visitors' Report for the year 1933 showed a substantial addition to the membership, the total (1020) at the end of the year, including honorary members, members and associate subscribers, being the highest reached since the War The following officers were re elected *President*, The Right Hon Lord Eustace Percy, *Treasurer*, Sir Robert Robertson, *Secretary*, Major Charles E S Phillips The fulfilment by the Trustees of the Rockefeller Foundation of their promise, made in 1930, to give £20,000 for endowment of research in the Davy Faraday Laboratory, was publicly announced some months ago In the Visitors' Report reference is made to this and other gifts to the Research Endowment Fund which has now been established at the Institution, and the Report of the Davy Faraday Laboratory Committee, which is printed with the Visitors' Report, gives interesting evidence of the work which is in progress with the funds now available from this and other sources

THE majority of the workers in the Davy Faraday Laboratory are engaged, under the direction of Sir William Bragg, in a combined effort to map out exactly the spatial distribution of the atoms in organic molecules", using X ray methods An X ray tube with revolving anti-cathode has been in regular use now for about two years, and a much larger tube, to operate up to about 50 kw, is in the experimental stages With these powerful sources, very small crystals can be used, and in recent work successful photographs have been obtained with crystals weighing less than one twenty fifth of a milligram From large numbers of reflection measurements calculations can be made, using a method based on the Fourier principle, of the electron density at every point within the crystal The result is given in the form of contour maps Each contour line shows the electron density expressed in whole numbers of electrons per cubic Angstrom unit The map is in general accurate to the width of a line " This interesting method of mapping the molecules is illustrated in the Report by a contour map of the durene molecule, taken from a recent paper by Dr J M Robertson, one of the workers in the Laboratory

Rotation of the Earth

ON May 1, a public lecture was delivered at Oxford by Dr J K Fotheringham, reader in ancient astronomy and chronology in the University, on the rotation of the earth Dr Fotheringham spoke of the importance of the fact of rotation in regard to such practical matters as the alternation of day and night, the march of the seasons, the tides, and the measurement of time Some of the Greeks, perhaps including Plato held the Pythagorean view that the earth and not the sky rotated, but in either case the rotation was generally held to be uniform The fact of precession was known to Hipparchus, but may be an older discovery A further disturbance of uniformity, namely, nutation, with a period of 19 years, was determined by Bradley at Oxford Since his time, further changes have been measured, such as a shifting of the position of the pole in relation to the earth's figure, this has a period of 15 months and may affect latitude to the extent of two fifths of a second of arc A change in the speed of rotation is no doubt a real physical fact, the day is getting longer by one second in many thousand years" The apparent acceleration of the sun is modified by that of the moon Fresh facts bearing upon this have been collected by Dr Fotheringham and others, but their full explanation awaits further research

Chemical Patents Committee

A CHEMICAL PATENTS COMMITTEE of the Department of Scientific and Industrial Research has been appointed to advise on the patenting and exploitation of results of the Department's chemical researches that may have industrial possibilities The Committee is the result of negotiations that have been taking place for some time between the Department and various industrial organisations with the object of promoting closer co operation and of avoiding unnecessary overlapping It is hoped that one result of the Committee's advice will be that research results may be brought to the notice of industry and translated into practice at an earlier stage than hitherto, and under conditions that will take existing industrial activities into account Sir Frank Smith, secretary of the Department of Scientific and Industrial Research, will act as chairman, and in addition to departmental members, the Committee will include Mr F H Carr and Mr J Davidson Pratt, representing the Association of British Chemical Manufacturers, and Mr J Arthur Reavell, representing the British Chemical Plant Manufacturers Association.

Scientific Progress and Employment

AT the recent annual meeting of the London branch of the Association of Scientific Workers, the chairman, Mr R W Western, read a paper on 'How Scientific Research may best help in the Present World Crisis" Mr Western pointed out that there is a widespread belief that the progress of science tends to create unemployment by substituting machinery for men and replacing highly trained operatives by unskilled labourers Innovations resulting from scientific research are generally found to have injurious secondary effects because (1) land formerly employed in production may be rendered useless, for example, that utilised for a railway is spoilt for other purposes while ferro concrete constructions cost nearly as much to demolish as to erect, (2) fixed capital sunk in superseded processes is rendered obsolete, (3) the number of workers required to produce a given output is reduced, (4) innovations may necessitate costly expenditure on advertisements to get the product known—but the trading community is reluctant to undertake this and prefers to advertise opportunities for gratifying wants already realised These considerations lend support to the view that what is most wanted are new ways of meeting unsatisfied needs by adapting available capital rather than innovations which save labour or supersede capital assets If an innovation founded on the results of scientific research is to produce good results, free from immediate drawbacks and therefore wholly beneficial at the present time, it should render possible the application of idle plant to the commercial utilisation of the waste products of existing processes by employing labour now surplus The best help that scientific research can give in the present crisis will consist in exploring the channels least subject to the drawbacks previously enumerated

Race and Culture in India

IT is not without interest to note that Dr J H Hutton's tentative correlation of race and culture in his Indian Census Report for 1931 not only receives commendatory reference but also is closely followed in method in the presidential address on Sramanism' delivered by Rai Bahadur Ramaprasad Chanda to the Anthropological Section at the recent Bombay meeting of the Indian Science Congress Analysing the concepts of Sramanism, which underlie the doctrine of renunciation, the animating principle of the mendicant and ascetic orders, the president showed that in early times the Vedic religion stressed the rites of the householder and had no place for the Sramanas, the forest dwellers and religious mendicants Hence he deduced that the Sramanas are to be derived from the pre Vedic, pre Aryan peoples and their practitioners of magic tracing the practice of asceticism back to the initiatory period of seclusion and abstinence of the shaman This interesting conclusion, which traces one of the most important elements in modern Hinduism to a non Aryan origin, is supplemented by further considerations bearing on certain of Dr Hutton s ethnological arguments which have been subjected to critical comment Ramaprasad Chanda suggests that the ingrained love of life disclosed by the religions of Saktism and Vaisnavism among the Bengalis, comparable to that found among the Aryans, is a racial psychological trait to be associated with the brachycephalic Bengali castes, the Indo Alpines, of whom Dr Hutton has suggested that they had acquired an Aryan language before they entered India Hence it is suggested, the strength of the Durga Kali cult in Bengal, which only in recent times has begun to give place to the renunciation of sramana

Palæolithic Gravels of Farnham

FOLLOWING the exhibition of Miss Garrod s finds on Mount Carmel a series of flint implements has been arranged at the British Museum to illustrate the sequence of industries in the terrace gravels south of Farnham Surrey Two cases at the head of the main staircase, in the Department of British and Mediæval Antiquities, contain not only a number of accurately located specimens in the Sturge collection as presented by Major A G Wade, but also maps and diagrams showing the terraces of the Wey and the Pleistocene history of the Farnham branch of that river The area has been recently surveyed by the Geological Survey (The Geology of the Country around Aldershot and Guildford, 1929), and Mr Henry Bury s papers in the *Quarterly Journal of the Geological Society* and *Proceedings of the Geologists Association* have been freely drawn on in order to explain the importance of this area for the dating of terrace deposits and the classification of implements It may be eventually possible to identify these four levels with the recognised sequence of terraces in the middle and lower Thames, and the local river captures should explain the presence of some types and the absence of others in the Blackwater and Wey valleys This exhibition will remain open until the middle of July

Recent Acquisitions at the Natural History Museum

IN connexion with the gorilla group to be arranged in the Upper Mammal Gallery, the British Museum (Natural History) has received from Mr Reginald Akroyd a quantity of vegetation collected during a trip which he made for this purpose to the Birunga Mountains, Uganda, last winter This vegetation consists of sections of trees, boughs of giant heaths and giant groundsels, a number of giant lobelias, ferns and tree ferns, and a large quantity of the arboreal lichen which is so characteristic a feature of these mountain forests The Zoological Department has recently received as a donation from the Rowland Ward Trustees a female specimen of a rare howling monkey (*Alouatta ursina*) from Brazil A male, presented by the same donors some years ago, is bright orange red in colour, whereas the female is brown Isolated crystals of native gold from alluvial deposits on the Muti stream, Buhweshu county, Uganda, have been presented to the Department of Minerals by Mr Michael Moses Two minerals new to science have been presented, namely, lusakite a new mineral composed of cobalt and aluminium silicate from 120 miles east of Lusaka, Northern Rhodesia, by Mr A C Skerl, and bismuth tungstate from Cornwall, by Mr E H Davison

THE Department of Botany has received the plants from Capt Kingdon Ward s recent expedition to Tibet The bulk of the collection is from north of Rima, north and south of the great snow range which runs approximately north west to south east In Zayul, south of the range the mountains are well wooded with deciduous and evergreen forest whereas in Nagong, north of the range, there is no forest It was possible to recognise three floral regions in Tibet, and the discovery that the snow range is an eastern extension is of considerable phytogeographical importance About 750 items were obtained and these include some new and interesting plants, and add to our knowledge of the distribution of many others The Department has received by exchange 536 San Thomé and Principe plants from Coimbra Many of them are duplicates of the types of a number of species not previously represented in the Museum collections From Edinburgh 1 423 specimens of *Rhododendron* have been received The majority of the species represented are new to the Museum collections and in many instances are portions of type collections

Palæontographical Society

THE eighty seventh annual meeting of the Palæontographical Society was held in the Geological Society s rooms at Burlington House on April 27, Prof W W Watts in the chair The Council s report recorded with regret the death of the president Dr F A Bather, and of one of the vice presidents, Dr F L Kitchin Since the last annual meeting some arrears of publication have been overtaken by the issue of two volumes of monographs Instalments of the monographs of Corallian Lamellibranchia, Gault Ammonites, Cambrian Trilobites and Dendroid Graptolites are included Another instalment of the monograph of Pleistocene Mammalia deals with the red deer, reindeer and roe Sir Arthur Smith Woodward was elected president, and Mr Henry Woods was elected vice president, Mr Robert S Herries and Dr C J Stubblefield were elected treasurer and secretary respectively The new members of Council are Mr A J Bull, Prof W T Gordon, Dr J Pringle and Mr W P D Stebbing

Natural Conditions of Soil Formation in India

AT the last meeting of the International Society of Soil Science it was decided to prepare a soil map of Asia, and the work of compiling the available materials was entrusted to a sub-commission headed by several of the leading Russian workers This subcommission has already published a number of contributions dealing with the soils of Japan, Manchuria and certain portions of China. A contribution by Dr Z J Schokalsky, published by the Academy of Sciences of the U S S R, Leningrad (1932), covers in a similar way the conditions in India The materials which have been in the hands of the author are so carefully worked out that it is hard to believe that the map has been made by one who has never visited India If it is open to criticism in certain directions this is only because the materials placed before Dr Schokalsky have been unsatisfactory and imperfect It must, however, be recognised that the references cited in the present contribution are far from complete and in a number of cases do not include the best materials available Thus, for example in connexion with the soils of north east India the whole of the admirable work done by the experts of the Indian Tea Association is omitted, though their studies are probably the best that have been done over a large area of Assam and Bengal Again, probably the best information about actual soil conditions and their distribution in peninsular India will be found in the various survey and settlement reports much of which is summarised in the Gazetteers issued more than a generation ago, and these do not appear to have been consulted A very large area in the north-east of the Peninsula, which forms perhaps the largest forest tract still existing in the country, is marked on the map as consisting of steppe soils Even with regard to the black cotton soil, or *regur*, the account given takes no account of the radically different types of the soil in the northern and the southern parts of the black soil area Before the present map is finally issued as an authoritative account of Indian soils, it will have to be subjected to very careful constructive criticism

Landscape Gardening

THE Institute of Landscape Architects is to be congratulated upon the appearance of *Landscape and Garden*, a new quarterly journal devoted to garden design and landscape architecture (vol 1, No 1, 1934, pp 74 2*s* 6*d*) The volume is edited by Mr Richard Sudell The Garden Theatre at the Herrenhausen Hanover, is described briefly by G A Jellicoe who shows by means of plans and photographs the lay-out of this very artistic piece of garden architecture R V Giffard Woolley contributes a helpful study on The Management of Small Spaces" Various considerations for the production of vistas, and the incorporation of stone paving and ornament are given A park to link Karlsruhe with the Rhine is described by P Morton Shand, and particulars of an interesting bird sanctuary are included Capt R C H Jenkinson writes about New Shrubs for Old", and in addition to describing several of the more recently introduced shrubs, discusses possibilities for their artistic grouping Birdseye' is a series of aerial photographs showing forms of community housing in England through the last five hundred years A J Cobb writes on 'Tree Surgery', outlining methods for the lengthening of life, or the complete repair, of damaged trees The use of focal points in design is very ably treated by Hervey Bennett, in an article entitled "Where Shall I Look ?" A series of photographs showing the illumination of gardens, together with a short description, are provided by Waldo Maitland Some very striking effects, produced by flood lighting trees, are shown 'Roof gardens, the Lungs of the Future" are given adequate treatment in an article by Lady Allen of Hurtwood, who introduces many practical suggestions One might advance the suggestion that the extremely small spaces' such as are included with the majority of present day houses might receive adequate treatment in future numbers, though the editor seems to be alive to this need A study of the development of the garden city' is promised for the next number (July)

Research on Oranges and Related Crops

THE British South Africa Co has issued a report on the activities of the Mazoe Citrus Experimental Station up to the end of 1932 (Oxford Univ Press, 192 pp) The Director, Dr W J Hall, and Mr W K Ford are engaged in a study of the citrus insects of Southern Rhodesia, and publish detailed descriptions of a considerable number of pests Soils of the Mazoe Estate are under investigation by Dr A A Morris who contributes a paper on the relation between soils and field practices Special attention has been devoted to irrigation cover crops and manures Problems of artificial coloration, maturity and transport wastage of oranges have engaged the attention of Mr G R Bates The work of the Station is comparatively recent, but the various problems are being studied with a detail which should ensure the production of valuable results

Electrical and Magnetic Units

BULLETIN No 93 of the National Research Council, Washington, reproduces the papers on units presented before the American Section of the International Union of Pure and Applied Physics at Chicago in June last After discussion it was recommended —that in view of the long use of the classical centimetre gram second units, no change should be made at present, but that the Gaussian system should be considered in future, that the practical units—ohm, volt, ampere, coulomb, farad, henry, joule and watt—might be extended into a complete absolute system either through the metre-kilogram-second or the centimetre-10^7 gm -second, the former by preference These proposals will in due course be considered by the Committee on Symbols, Units and Nomenclature established by the International Union

Health of the British Army during 1932

LIEUT GEN H B FAWCUS, director general of the Army Medical Services, states that the health of all ranks throughout 1932 was satisfactory ("Report on the Health of the Army for the Year, 1932" London H M Stationery Office, 1934 2*s* 6*d* net) The admission rate to hospital, 412 5 per 1,000 of the strength, was the lowest on record, and the invaliding and constantly sick rates were also the lowest recorded since the War All the more important diseases have shared in the decline, namely, malaria, dysentery, influenza, tonsillitis, venereal diseases and others In consequence of the high incidence of tonsillitis over many years, a Joint Medical Services Committee has studied the subject, but without reaching any very definite conclusion as to causation or prevention A summary of research work is given in the report

German Exhibition of Chemical Plant

'ACHEMA" is the Ausstellung für chemisches Apparatewesen, the seventh of which is to be held at Cologne on May 18–27 under the auspices of 'Dechema", the Deutsche Gesellschaft für chemisches Apparatewesen In anticipation of this exhibition the Achema Jahrbuch 1931/1934, a report of some 230 pages on the position and development of the study and construction of chemical plant, has recently been published by Dechema at Seelze bei Hannover Those who are interested in the exhibition and apply before May 10 can obtain a copy of the Jahrbuch, which is priced at 10 m , on sending only 0 40 m to cover the cost of postage The "Wissenschaftlicher Teil" includes articles on the development of technique and plant construction, on standards in apparatus, on welding in the building of chemical plant, on instruments for the measurement of therapeutically active ultra violet light emission, and on the Drawinol process for dehydrating ethyl alcohol The Technisch industrieller Teil' contains information concerning constructional materials, laboratory apparatus, technical apparatus, plant and machinery The book serves also as a guide to the exhibits We are reminded that in describing the sixth exhibition held at Frankfurt am Main in 1930 we said that there could never have been a more comprehensive show of aids to chemical manipulation, at Cologne 300 firms will exhibit more than 2,000 types of apparatus and plant, so that the forthcoming exhibition is unlikely to be less valuable and impressive

Congress of History of Medicine

THE International Society of the History of Medicine has received an official invitation from the Spanish Government to hold its tenth congress at Madrid in the second fortnight of September 1935 The following subjects, of which the executive committee has to select two, have been suggested for discussion Spanish colonial medicine, Pre Columbian medicine, the history of syphilis, medical folk lore, and the introduction of biological ideas into the domain of history, a subject proposed by Prof E Jeanselme of Paris This Congress of 1935 must not be confused with that organised by the International Academy of the History of Sciences, which will be held this year at Barcelona, Madrid, Toledo, Coimbra and Lisbon, on September 19–October 2

Television Inquiry

THE Postmaster General stated in the House of Commons on April 30 that he hoped to announce shortly the composition of a committee which will advise on the conditions under which any public television service should be provided It is understood that the Committee to be appointed will consist of representatives of the Post Office, the British Broadcasting Corporation and the Department of Scientific and Industrial Research

Announcements

DR JOSEPH PEARSON, who recently resigned his post as director of the Colombo Museum and marine biologist to the Ceylon Government, has been appointed director of the Tasmanian Museum, Hobart, as from March 1 last

AT the meeting of the London Mathematical Society to be held on May 17 at 5 p m in the rooms of the Royal Astronomical Society, Burlington House, Prof E A Milne, of Oxford, will give a lecture on World Gravitation by Kinematic Methods"

THE Institution of Civil Engineers has awarded a Charles Hawksley Prize of £150 for 1934 to Mr H G Cousins, for his design of an aerodrome The prize is awarded for the best design of an engineering structure combining artistic merit with excellence of constructional design, and the competition is open to students and associate members of the Institution less than thirty years of age

KEDDEY FLETCHER WARR Studentships of the University of London, each of the value of £210 a year for three years, have been awarded to Dr E G Jones, for the continuation of research in spectroscopy, and to Dr A C Offord, for the continuation and extension of research in pure mathematics

THE Frazer Lecture, founded in honour of Sir James Frazer, is delivered annually at the Universities of Oxford, Cambridge, Glasgow and Liverpool in turn, and this year goes to Oxford for the fourth time It will be delivered on May 10 at 5 30 p m in the Examination Schools, Oxford, by Prof H J Rose, of the University of St Andrews, who will take as his subject "Concerning Parallels"

THE Association of Special Libraries and Information Bureaux (ASLIB) will hold its eleventh annual conference at Somerville College, Oxford, during the week end beginning on September 21 Particulars may be obtained from the Secretary of the Association, 16, Russell Square, London, W C 1 Sir Richard Gregory has agreed to accept nomination as president of the Association for 1934–35

THE Rockefeller Medical Fellowships for the academic year 1934–1935 will shortly be awarded by the Medical Research Council, and applications should be lodged with the Council not later than June 1 These Fellowships, of the annual value of £350, are awarded to graduates who have had some training in research work in the primary sciences of medicine, or in clinical medicine or surgery, and are likely to profit by a period of work at a university or other chosen centre in the United States before taking up positions for higher teaching or research in the British Isles Full particulars and forms of application are obtainable from the Secretary, Medical Research Council, 38 Old Queen Street, Westminster, S W 1

THE 'Handbook of the Collections Illustrating Electrical Engineering" (Science Museum, South Kensington Part 4) (H M Stationery Office 2s net) gives the substance of the detailed descriptive labels associated with the exhibits in the Electric Power Collections in the Science Museum By means of asterisks, attention is directed to the more important exhibits which have influenced future developments It will be most useful to those who desire to study the historical development of the use of electric power

MESSRS OPPENHEIM AND CO (RARE BOOKS), LTD , 174 Fulham Road, London, S W 10, now in liquidation, have issued a special sale catalogue of journals and periodicals of British and foreign learned societies The list includes long runs and shorter sets of publications on most branches of science, natural history, medicine, engineering and economics Among the more important items is a complete run of the *Annals and Magazine of Natural History*, from the commencement in 1838 to 1927, to be had for the bargain price of £115 This is a low priced list which should appeal especially to librarians

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —An assistant lecturer in metallurgy in the University of Manchester—The Registrar (May 7) An engineer and surveyor to the Brentwood Urban District Council—The Clerk of the Council, Council Offices, Brentwood (May 7) A lecturer in engineering at the Wigan and District Mining and Technical College—The Principal (May 7) An assistant master to teach two of the following subjects machine drawing, mechanics, physics, mathematics, at the Portsmouth Junior Technical School—The Town Clerk, Guildhall, Portsmouth (May 10) A principal of Kilburn Polytechnic—The Secretary, Middlesex Education Offices, 10, Great George Street, Westminster, S W 1 (May 16) An assistant lecturer in physics in the University of Manchester—The Registrar (May 26) A teacher of electrical engineering at Dartford Technical College—The District Secretary, Education Offices, 15, Lowfield Street, Dartford (May 26) A headmaster of the Ashton under Lyne Junior Technical School—G W Handforth, Education Office, 8, Warrington Street, Ashton under Lyne (May 26) An Imperial mycologist at the Imperial Institute of Agricultural Research, Pusa, Bihar and Orissa, India—The High Commissioner for India, General Department, India House, Aldwych, London, W C 2 (May 31) An assistant engineer to the Water and Sewerage Board, Corporate Area of Kingston and St Andrew, Jamaica—The Crown Agents for the Colonies, 4, Millbank, London, S W 1 A woman tutor in mathematics at the Edge Hill Training College, Ormskirk—The Principal

Letters to the Editor

[*The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE *No notice is taken of anonymous communications*]

Magnetic Properties of Supraconductors

I SHOULD like to report the results of experiments which bear on the recent discovery of Meissner and Ochsenfeld, regarding the magnetic properties of matter in the supraconducting state I feel that our results will add something to this original contribution and the further contribution made recently by Mendelssohn and Babbitt[1]

According to Meissner's results if a supraconductor be lowered from a temperature above the transition point to a temperature below that point, with a constant magnetic field applied, we should expect to observe a change in flux in search coils placed in various positions relatively to the supraconductor and the field A supraconducting body in the shape of a hollow cylinder of tin was used, and small coils wound about the tin or placed near the tin, as indicated in Fig 1 Coil No 1 was wound around one side of the cylinder Coil No 2 was placed inside the hollow cylinder Coil No 3 was placed near the surface of the cylinder tangential to the applied field Coil No 4 was wound so as to enclose the whole cylinder in the plane of the coil No 5 was placed at the outer surface of the cylinder perpendicular to the applied magnetic field According to the results reported by Meissner, if one applies a magnetic field when the tin is above its supraconducting point, and leaves this field constant while the temperature of the sample is taken through its transition point to a temperature definitely below the supraconducting temperature, one should observe the following In coil No 1, decrease to zero flux, in coil No 2, no change in flux, in coil No 3, increase of twice the applied field intensity, in coil No 4 decrease in flux due to wiping out of the flux in tin, in coil No 5, decrease to zero flux

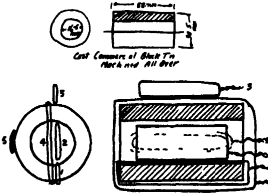

FIG 1

In our experiments these search coils were arranged to be connected directly to a flux meter, and the deflections were read by means of a lamp and scale Our preliminary results, which have been checked two or three times, are as follows As the tin cylinder was taken from above the transition point to below, coil No 1 showed a decrease of 90 per cent in the flux, No 2 showed a slight increase up to 10 per cent, coil No 3 showed an increase of 25 per cent, coil No 4 a decrease of 30 per cent, and coil No 5 a decrease of from 20 to 25 per cent in the flux It should be noted that coil No 3 projected about 5 mm from the surface where there was undoubtedly a magnetic field of high gradient and also that coil No 5 of necessity enclosed a considerable space where the field was not theoretically zero, but only relatively weakened The field strengths used were approximately 30, 150 and 200 gauss respectively Repeated readings were carried out with the stronger field

This work was carried out with the assistance of Mr J O Wilhelm and Mr F G A Tarr

Constitution of Hafnium and other Elements

TAKING advantage of the exceptionally favourable setting of the anode discharge tube used in the analysis of the rare earths already reported[1], I have obtained further results of great interest

Hafnium gives a mass spectrum indicating five isotopes, a weak line at 176 and four strong ones, 177, 178, 179, 180, of which the even numbers are rather more abundant Thorium appears to be simple 232, no line of higher mass number could be seen Rhodium gave the feeblest effect of any element yet analysed, only one line, that expected at 103, could be clearly detected

Very intense spectra were obtained from calcium, disclosing faint new isotopes, 42 and 43, in addition to 40 and 44 previously discovered by Dempster It also appears very probable that a line at 41 was partly due to an isotope of calcium, but the difficulty of making an accurate estimate of its intensity and the impossibility of entirely excluding potassium are obstacles still in the way of a definite proof of this interesting conclusion

Numerous attempts to analyse titanium in the past have yielded very inconclusive results Satisfactory mass-spectra have now been obtained which show its main line, 48, flanked by four new faint lines, 46, 47 49, 50, the whole forming a most striking symmetrical group It is noteworthy that with the discovery of these isotopes and that of argon 38 recently reported by Zeeman, all the numbers from 9 to 56 are now filled

New mass spectra obtained from zirconium not only show an additional and fairly abundant isotope 91, hitherto overlooked owing to insufficient resolution, but also confirm the presence of the very rare and previously doubtful constituent 96, which is of particular interest, as it forms with molybdenum and ruthenium the lightest known isobaric triplet

Further work with samarium has disclosed two faint isotopes, 144 and 150

Only four common elements, palladium, iridium, platinum and gold, still remain to be analysed, even with the present setting, all attempts with these have given negative results

Small Angle Scattering of Electrons in Helium

IN July 1933[1] one of us (R W), in collaboration with T Emmerson and J E Taylor, pointed out that, in agreement with Mr S N Van Voorhis[2], we had been obtaining curious scattering effects using narrow electron beams passing through helium at low pressures

The effect, which was very marked at energies of between 100 and 200 electron volts, consisted in a very obvious maximum in the number of inelastically scattered electrons at a few degrees out from the main beam This result was so remarkable and unexpected as to demand further and much closer examination and with that end in view a special apparatus has been set up in this laboratory

Briefly, the electron gun is rotated slowly and continuously by a synchronous electric motor, the scattered electrons after passing through a slit system, being analysed by a magnetic field and the resulting spectrum recorded on a photographic film kept in continuous motion by a second synchronous motor The result is a continuous record of all the scattered electrons both elastic and inelastic over the desired angular range, energy and number being simultaneously recorded in terms of position on the film and photographic density respectively

The photograph here reproduced as Fig 1 indicates the elegant kind of record which can be obtained by this method The two separate spectra show the variation in probability up to 10° from the main beam of elastic impacts, and those which have resulted in the two most likely transitions ($2P$ and $3P$) At the top of the record are to be seen four wavy traces which have been produced by sweeping the electrons (at zero beam setting) rapidly across the film with a time marking device By suitably accelerating the motion, a range of wave lengths can be obtained, as shown, from which density intensity information can be derived for interpreting the spectral traces themselves

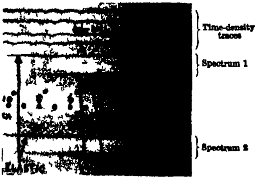

FIG 1

The anomalous results previously reported have not, so far, been confirmed with this more refined apparatus

We have measured the relative probabilities of the elastic and inelastic ($2P$) collisions at angles up to 10° at energies of impact varying between 100 and 400 electron volts with the results shown in Fig 2 Here the inelastic probabilities given by the most recent form of theory (Massey and Mohr)[3] have been taken as the basis and in agreement with our experimental results (full curves marked $2P$) It will be seen how very different are the calculated (full lines) and experimental (dotted lines) values for the elastic probabilities In particular, at the lower impacting energies this divergence is specially remarkable

Galvanometer Amplification by Photo-Cell

IN 1931[1] I described the use of a differential photo electric cell connected to a secondary galvanometer for amplifying the movements of a primary one The only suitable cell available then was a cuprous oxide one, and the current produced by it was not great enough to allow a quick (and therefore insensitive) secondary galvanometer to be used, consequently, although sufficient amplification was obtained, the movements were slowed This slowing of movements is an even greater objection to the thermal relay of Moll and Burger since the thermocouple introduces a further lag which the photo-cell does not

I have recently tested a Weston 'photronic' cell for the same purpose This cell was opened and a groove cut down the centre of the disc Lead fuse wires were then inserted to make contact with the faces of the two halves These lead wires were joined to terminals by which the cell was connected to a Kipp micro galvanometer of period 0 2 sec With this a five to tenfold amplification can be obtained of a galvanometer of 1 5–5 sec period, without introducing any measurable lag into its movements A Moll galvanometer of 1 25 sec period used in place of the microgalvanometer as a secondary would give a further fourfold multiplication an amplification of at least twenty times It would still introduce little lag into the movements of the primary one

By this means any galvanometer of sufficient steadiness can have its figure of merit increased many times For those who can go to the trouble and expense of using a second galvanometer of short period and a photo cell the problem of sensitive galvanometers is reduced largely to one of steadiness and zero stability, given those amplification with a photo cell can supply the required sensitivity—to the limit of course set by Brownian movements of the primary galvanometer

Diffraction of Cathode Beam by Simultaneous Reflection from two Different Specimens

FROM the first investigations of G P Thomson[1] dealing with the structure of surface layers up to the present time the method of using a specimen ground flat has remained apparently without change[2] though the construction of a crystal holder for this method is comparatively complicated and the results obtained in such a way cannot apparently be of high degree of accuracy The investigation of the surface structure by reflection is, however, of great interest We have recently succeeded in obtaining very exact results by means of a simultaneous reflection of a cathode beam from two specimens, one of them was a substance the lattice constants of which were very exactly known, such as sodium chloride

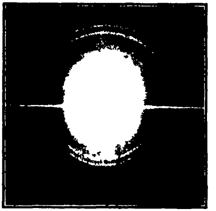

FIG 1

As has been shown by H de Laszlo and V Cosslet[3] the cathode beam is hollow The results of our study confirm this Therefore for obtaining a sharply outlined diffraction pattern it is evidently not necessary to use the entire cross section of the cathode beam, but only one side of it, and this can be done only with a convex specimen From Fig 1 it can be seen that this method not only gives a sharp diffraction pattern, but also simultaneously a very sharp spot from the cathode beam may appear in the photographic plate, so that the centre of the rings can be found at once If a cathode beam is passing between two such convex specimens (Fig 2) a double diffraction pattern appears as is shown (Fig 1)

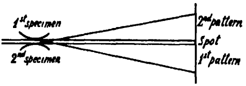

FIG 2

When compared with the method of taking successive photographs one after the other[4] we believe our method has the advantage that the possible change of high voltages is with simultaneous exposures of no importance Moreover the mounting of such a double specimen and its setting in the beam is exceedingly simple

A fuller account of this method will be published shortly

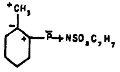
The Polarity of the Co-ordinate Link

IT has already been shown[1] that organic sulphides and tertiary arsines differ markedly in their reaction with chloramine T The former give rise to sulphilimines of formula $R_2S \rightarrow NSO_2C_7H_7$, in which the co ordinate link is apparently devoid of polar properties the arsines however, do not give stable arsinimines of formula $R_3As \rightarrow NSO_2C_7H_7$ because the co ordinate link in such compounds apparently possesses sufficient polarity to combine with water, producing thus the corresponding hydroxy sulphonamides, $R_3As(OH)\,NHSO_2C_7H_7$ This behaviour is similar to that of the tertiary arsine oxides, $R_3\overset{+}{As} \rightarrow \overset{-}{O}$ where the strongly polar link induces ready combination with water to give the dihydroxides $R_3As(OH)_2$

We are undertaking a systematic study of the action of chloramine T on the organic derivatives of the elements of Groups 5 and 6 and the tertiary phosphines in this respect come midway between the sulphides and the arsines, the final product depending primarily on the nature of the tertiary phosphine Thus tri *o* tolylphosphine gives a true phosphinimine, $(C_7H_7)_3P \rightarrow NSO_2C_7H_7$, (*A*), and no other product has been detected tri-*p* tolylphosphine gives a mixture of the phosphinimine isomeric with (*A*) and the corresponding hydroxy sulphon amide, $(C_7H_7)_3P(OH)\,NHSO_2C_7H_7$, (*B*) Tri *m* tolyl phosphine apparently gives no phosphinimine, the only product isolated being the hydroxysulphonamide isomeric with (*B*)



These results are apparently determined chiefly by the position of the methyl group relative to the phosphorus atom. The co ordinate link in (*A*) will tend to give the P and N atoms a weak positive and negative charge respectively, $(C_7H_7)_3\overset{+}{P} \rightarrow \overset{-}{N}SO_2C_7H_7$, simultaneously, however, the polarity induced by the three *o* methyl groups will tend to give the *P* atom a negative charge The polarity of the co ordinate link is thus suppressed and a stable phosphinimine results In the *p* compound, the effect of the methyl groups is similar but, owing to the greater distance involved, definitely weaker hence the formation of both the phosphinimine and the hydroxysulphon amide In the *m* compound however, the polarity induced by the methyl groups reinforces that of the co ordinate link, and therefore, as with the arsines, the hydroxysulphonamide alone results

This interpretation of our results obviously requires considerable further confirmation, which we are now seeking with aromatic phosphines containing other electropositive or electronegative groups mean while, aliphatic phosphines apparently all give stable phosphinimines We are also attempting to prepare a dissymmetric phosphinimine, $R_1R_2R_3P \rightarrow NSO_2C_7H_7$, in which R_1 contains an acidic or basic group for salt formation since such a compound should clearly be capable of resolution into optically active forms

Multiple Laue Spots from Aluminium Crystals

INVESTIGATING the distribution of the intensity along the Laue spots from thick (6 mm) deformed aluminium crystals, we have found that it depends strongly upon the degree of the plastic deformation The spots from a thick undeformed crystal are elongated radially and uniformly black (Fig 1) Each portion of the spot is formed by rays reflected from a corresponding region of the crystal along the beam The spots from the same crystal only slightly plastically deformed (0 5 per cent) are no longer uniformly black (Fig 2) The blackening increases on the ends of all spots and also in the inner parts of several spots The spots become double or triple and similar to the multiple spots which have been described in other investigations[1] This result indicates that the exterior layers, and certain layers situated inside, scatter more energy and therefore are more imperfect than other layers We conclude that the degree of the plastic deformation and, therefore, the distribution of the residual stresses along the path of the beam are not uniform The dependence of the doubling on the distance from the crystal to the photographic plate is an indication of the focusing property of the differently oriented blocks, situated along the path of the beam (the beam was one of small divergence) It seems that multiple Laue spots which have been described in previous investigations[1] may be due to the reversible or irreversible changes of the perfection of the crystals and also to the focusing in the case of the deformed crystals

Height of the Aurora in Canada

DURING the winter of 1932 33, a number of measurements of the height of the aurora borealis were made at Saskatoon (lat 52 07′ 53″ N , long 106° 37 47″ W) It was found that the height at which the lower limits of the auroral arcs and bands were most frequently seen was 105 km , a value in close agreement with that found by Størmer and others in Norway Fig 1 shows the distribution curve, the number of auroral points measured being plotted against their height in kilometres In plotting this curve, 220 points were used and they were taken in 5 km groups

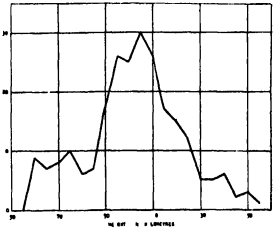

FIG 1

Størmer[1] has stated that the lower limit of height observed in Norway is 80 km In connexion with this, our observations of April 16 and April 20, 1933, are particularly interesting On these two occasions bands were photographed the lower limits of which were at a height of only 60 km Thirty seven measurements were made on auroral features the heights of which were less than 80 km, and eighteen of these showed heights of less than 70 km, the lowest recorded being 59 km In these photographs the intensity was good and the edge of the aurora clearly defined The calculations were made by the network chart' method of Harang and Tonsberg[2], and the direction of the displacement of the aurora relative to the fixed stars was quite favourable The length of the base line used for the photographs was 112 km

In addition to the results described above, several measurements were made on long ray structures in the aurora One of these was found to extend from a height of 336 km at its upper limit to a height of 71 km at its base, while a second extended from 155 km to 74 km It therefore appears that, in Western Canada, the lower limit of the auroral displays is nearer to the earth s surface than in Norway

These results will be published in detail later as part of the Canadian contribution to the International Polar Year work

Meteorology of a Gliding Flight

As meteorologists have shown a certain amount of interest in the experience of glider pilots, the following brief account of my flight from Dunstable to Rayleigh in Essex, on April 22 may be worth recording

The flight was made in a high performance sailplane the Rhönadler 32, hand launched from Dunstable Downs, which at this point rise some 200 ft above the surrounding country and about 850 ft above sea level The wind direction was approximately due west and velocity about 8 m p h At 10 30 a m cumulus clouds formed rapidly, and on taking off at noon the sky was three quarters covered with this type The instruments carried were a barograph, an altimeter, air speed indicator, variometer and compass

After slope soaring for a few minutes at a height of only 100 ft I detected the rising current under a small cumulus and promptly circled in the manner of the convection soaring birds The machine rose steadily some 2,000 ft, when I decided to fly up wind under a much larger cloud which appeared to be in the process of formation This decision proved very beneficial, as only a few hundred feet were lost in the journey, and height was very rapidly regained under the cloud At 3,500 ft I entered the cloud base and thus commenced my first cloud flight with neither parachute nor appropriate instruments—a distinctly stirring experience The rising current inside the cloud was considerably more violent than underneath it, so much so that one felt definitely forced into the seat Unfortunately, my variometer, an experimental type, was not working very well so I cannot say what was the maximum rate of climb I emerged from the side of the cloud at approximately 5,000 ft above the start in brilliant sunshine and steered in a south easterly direction, finally landing near Southend, an approximate distance of 54 miles from the start

The flight could undoubtedly have been prolonged but for the fact that London's smoke caused a thick haze, and the cloud form degenerated into a stratiform type with only a weak rising current

The lowest altitude recorded was 1,200 ft, but circling under and into a cloud again restored me to 5,000 ft

Perhaps meteorologists could tell us if a sensitive thermometer would be useful in detecting rising air and also indicate, generally, how sailplane pilots can assist the science of meteorology

Field Studies and Physiology: a Further Correlation

In a previous letter to Nature[1] one of us directed attention to certain striking correlations between the findings independently arrived at by physiologists in the laboratory and students of bird behaviour in the field Since then a further parallelism has come to light which it seems of sufficient interest to record Wiesner and Sheard[2] state that partial removal of the prepituitary in adult male rats usually results in what they style partial diserotisation' The normal copulatory process consists in a definite and rapid sequence of acts In partially hypophysectomised males, the sequence is usually slowed down and interrupted, consisting merely of hesitant acts of mounting, often abortively repeated many times

Observations on moorhens (*Gallinula chloropus*) show that behaviour of a similar nature is often encountered in the wild state Here too the normal male mating process consists of a sequence of actions usually performed very rapidly so as to appear like a unitary act During cold disagreeable weather, however, the sequence is often much slowed down, and interrupted in the middle For example, after mounting on the female's back, the male may appear confused, and after an interval of hesitation descend without proceeding further Or the sequence may be interrupted earlier, for example, after the male has merely placed a foot on the female's back A curious fact is that such incomplete sex behaviour usually ends in the male viciously pecking the female

Such behaviour is to be observed in the same birds which on previous fine days had been mating normally The cold appears to act more or less quantitatively, very cold weather entirely extinguishing all sexual behaviour, moderate cold inducing only slight 'diserotisation' Poultry keepers are familiar with similar effects of cold weather on cocks

Pavlov[3] has observed similar phenomena in non sexual reactions in his experimental dogs, both as regards the dissociation of acts normally associated, and in the slowing down and the meaningless repetition of acts In addition, 'negativism', a negative reaction to a stimulus which usually induces a positive reaction, is often seen this may be compared with the male moorhen's incomplete sexual behaviour terminating in an attack on the female Pavlov speaks of these phenomena as hypnotic, and ascribes them to special types of spread of inhibition in the cortex

We *have thus similar modifications of normal* action due in one case to glandular deficiency in another to depressant external conditions and in a third to psychological causes Further investigation of such phenomena, whether in the field or the laboratory, should be of great interest for the science of animal behaviour

Rings of Cork in the Wood of Herbaceous Perennials

APPARENTLY the only plants reported to have successive rings of true cork in the wood are certain species of *Sedum*[1,2] There are, however, the closely related cases of *Gentiana cruciata*, *Aconitum Lycoctonum*, *Salvia* spp[3], *Delphinium* spp[4,5] and *Mertensia* spp[6], in which cork develops to some extent in the xylem but is rarely found there in the form of concentric layers In these plants, as also in *Sedum* spp internal cork is said to arise in connexion with the splitting of the rhizome or root into strands and the segregation of vascular bundles directly connected with effete leaves and annual shoots There are also on record[7] examples of localised and anomalous cork layers round groups of vessels in the wood of various species Finally there is the case recently described by Lemesle[8] of concentric suberised layers in the wood of *Hymenocrater* spp , but here, no cork cambium is formed and the suberised layer is properly described by Lemesle as a pseudoperiderm

My discovery of concentric rings of periderm as a constant feature, in the wood of older subterranean organs of several herbaceous perennials, namely *Epilobium angustifolium*, L *E latifolium* L *Gaura coccinea* Nutt and *Artemisia dracunculoides*, Pursh is therefore of interest In the first of these species the horizontal roots, likewise the underground stumps' of former aerial stems, may live for many years, and each year may send up flowering shoots As many as twenty concentric rings of periderm have been observed in the wood of old roots, while numbers ranging from one to ten have been commonly encountered The wood of this species includes not only vessels and fibres but also a large proportion of phloem and parenchymatous elements Each summer a zone of periderm arises in the parenchymatous part of the wood formed near the close of the previous summer, or less frequently in a more deep seated position in the wood When mature this interxylary periderm commonly consists of two or three layers of cork cells with alternating layers of non-suberised cells

The point of chief interest here is the development of interxylary periderms in relation to the dying down of flowering shoots and the origin of new annual shoots Each new interxylary periderm arises in June, between the wood that served last year's aerial stem and the thin sheet of new wood connecting with the young shoots Above the point of insertion of the uppermost of the new shoots, very little, if any new xylem develops, and in that region this internal periderm makes connexion across the phloem with an external periderm Furthermore, the interxylary periderm extends as a continuous layer *throughout the entire subterranean system* with the exception of the younger roots As a consequence, the various tissues in direct connexion with the new shoots are segregated by a barrier of cork from necrotic tissues as well as from the older wood The younger parts fitting in sleeve like fashion over the older decadent cylinder are therefore protected against possible desiccation and invasion of destructive organisms For as the stump of a floral shoot disorganises a broad hollow path bordered mainly by soft tissues becomes exposed to various external agencies Thus *the interxylary periderm* may function in somewhat the same way as does suberised tissue below the abscission layer of a leaf Persistence of plants in particular locations may be largely due to the protection afforded by this internal suberised barrier

In both species of *Epilobium* and in *Gaura coccinea*, fission of older roots into strands commonly occurs This phenomenon is related to the occurrence of concentric rings of interxylary cork and to the mode of production and dying back of shoots and of rootlets Nevertheless fission in these species differs in certain important respects from all previously described examples[2,3,4,5,6] of this phenomenon

The discovery of interxylary cork reported here raises questions regarding the general occurrence and the significance of the internal suberised barrier as well as questions concerning the physiology and ecology of perennating herbs devoid of this structural feature I would welcome references to literature and comments bearing upon these problems Detailed descriptions of the subterranean organs of the species in hand are now being prepared for publication

The Neutrino

ALTHOUGH it seems very unlikely that neutrinos, after having been emitted in a nuclear process, give rise to any detectable ionisation[1], we would like to point out that it is not impossible in principle to decide experimentally whether they exist

One possible experiment would be to check the energy balance for the artificial β decay Take, for example, the process

$$B^{10} + \alpha \rightarrow N^{13} + \text{neutron}$$
$$N^{13} \rightarrow C^{13} + e^{+} + \text{neutrino}$$

One can safely assume that if the positive electron is emitted with the greatest possible energy, the kinetic energy of the neutrino will just be zero The balance of energy in this case will therefore determine the mass of the neutrino For this purpose one would have to know the mass defects of B^{10}, C^{13} and the neutron* the kinetic energy of the α particles and the neutrons and the upper limit of the spectrum of the emitted positive electrons

A second way of deciding the question would be to observe the recoil of the nucleus in β decay With natural β rays this is in practice impossible because the recoil energy is too small but the nuclei involved in artificial β decay are much lighter The kinetic energy of recoil of a disintegrating N^{13} nucleus would be of the order of some hundreds of volts if there were no neutrinos If the neutrino hypothesis is correct there would be a defect of momentum which would be uniquely connected with the lack of observable energy in each individual process

In addition to the nuclear processes mentioned in our previous communication it may also be expected that a nucleus catches one of its orbital electrons decreases by one in atomic number and emits a neutrino (A corresponding process with increase in atomic number is not possible because of the absence of positive electrons) This process further limits the possible mass differences between stable neighbouring isobares and particularly between neutron and proton If the hydrogen atom is to be stable we must have (for the masses)

$$\text{Proton} + \text{electron} < \text{neutron} + \text{neutrino}$$

The probability of such a process is less than that of a process involving emission only the energy of the neutrino being the same The reason is that the momentum of the electron which enters in the third power is about a hundred times smaller But even for a surplus energy of 10^{5} volts the life period of hydrogen would be only 10^{18} years which seems incompatible with experimental facts If therefore the neutrino is not heavier than the electron the neutron must be at least as heavy as the proton

H BETHE
R PEIERLS

Physical Laboratory
University Manchester

* The accuracy with which the mass of the neutron can be determined at present is, however far from being sufficient for this purpose H Bethe and R Peierls NATURE 133 532 April 7 1934

Optical Constants of Alkali Metals

A NUMBER of recent researches[1] have shown that electrons in some metals—in the first place in alkali metals—can be considered with sufficient approximation as free The transparency of alkali metals in the ultra violet region discovered by Wood[2] has been recently explained by Zener[3] from the point of view of free electrons Immediately after the publication of Zener s communication we calculated the optical constants n and k of the alkali metals using the free electron gas model and taking into account the collisions of the electrons with the atomic lattice and we obtained satisfactory agreement with the measured values

Kronig in a recent letter[4] states that the calculation of the optical constants of alkali metals can be carried out with the help of the formulæ of his dispersion theory in metallic conductors if one takes into consideration only the free electrons In connexion with this it is interesting to note that our calculations based on the simple Sommerfeld theory of metals give the same results as can be inferred from the comparison of our results with the numerical values published by Kronig Our calculations have been made taking into account (1) the motion of free electrons under the influence of the variable external field (2) the collisions which stop this motion The average velocity of electrons was calculated in just the same way as in the Lorentz theory of the collision damping With this average velocity the current is obtained which is substituted in Maxwell s equations The complex dielectric constant is given by the final formula

$$\varepsilon = 1 - \frac{\omega_0^2}{\omega^2}\,\frac{(\omega\tau)^2}{1+(\omega\tau)^2} + i\,\frac{\omega_0^2}{\omega^2}\,\frac{\omega\tau}{1+(\omega\tau)^2}$$

where $\omega_0^2 = 4\pi N e^2/m$ and τ is the time between two successive collisions of the free electron with the lattice calculated according to the Sommerfeld formula from the specific conductivity The formula contains two parameters which are determined by non optical measurements (1) the specific conductivity σ (2) the number of electrons N per

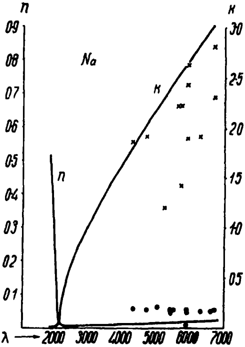

FIG 1

cm³ Putting $\varepsilon = (n - ik)^2$ we obtain n and k represented for the case of sodium by the curves in Fig 1 Dots and crosses denote the measured values[5] n and k

The scattering of experimental values is very large which is explained by the low accuracy of measurements due to the difficulty of preparing a clean metallic surface For potassium the agreement with regard to n in the region of small values is somewhat worse but the order of magnitude remains the same The values of k in this case came out better than for sodium When $\omega\tau < 1$ our formulæ go over into the classical expressions of Drude

Pathology and Deformation in Ancient Egypt. A theory to account for the peculiarities of the human body as depicted in the art of Amarna recently put forward by Herr Felix Proskauer is discussed by Dr. Edith M. Guest in *Ancient Egypt and the East*, 1933, Pts. 3, 4. The theory in question suggests that rickets was widespread in Egypt from the time of the Heliopolitan priesthood, who derived their influence from the discovery of the healing powers of the sun, this also explaining Akhenaton's devotion to sun worship. As against this theory, it is pointed out that neither was the anti-rachitic vitamin D likely to have been deficient in the food of the ancient Egyptians nor were the conditions of their life such that they would have suffered from a deficiency of sunlight owing to avoidance of excessive heat. The dwarfism, of which there are representations in Egyptian art, is not rachitic but achondroplastic. Five, and probably all six, of the representations of dwarfs at Amarna exhibit the inward turning feet due to talipes, which is of a pathological origin quite different to rickets. Turning to the evidence of osteology, among the thousands of skulls which have been examined, there is no evidence of rickets. It is suggested that the peculiar head form of the royal family is an inheritance of hyperdolichocephaly due to a deformation of the pelvis; but there is no evidence to support the view that hereditary dolichocephaly could be produced in this way, or that a flat pelvis prevailed at any time in Egypt. The figures given by Dr. G. M. Morant from early predynastic to Roman times show no evidence for any progressive rachitic dolichocephaly. Although owing to the destructibility of the pelvis the evidence is not exhaustive, no flat pelvis has been recorded. The exaggerated female waist found in certain of the Amarna figures is probably due to a ritual dress.

Seasonal Festivals in Sumeria, Persia and India. In the *Indian Antiquary* for December, Dr. B. C. Mazumdar institutes a comparison between two Hindu social customs and the Babylonian and Persian Sacæa with the view of illustrating the historical significance of the former. Of these, one is a very ancient custom obtaining in the Chauhân ruling houses of Sonpur and Patna in western Orissa, the object of which is to give a fresh lease of life to the ruler in a magical way. In the bright fortnight of the lunar month of Âśvin, a Brahmin goes out riding on a pony, declaring that he has become ruler of the territory. He returns to the palace to doff his authority in a ceremonial at the close of which the rajah takes his place. It is to be noted that the Sumerians began their year in the autumn, just as in ancient India, where the carnival of the 'Lord of Misrule' took place. In this festival a pseudo-king was set up during the five or six days of the carnival, and on the final day he was hanged or scourged. At a later period, in Babylonia and Assyria the New Year was transferred to the spring; but the old calculation was retained and there were thus two New Year festivals, the custom also passing into Persia. The Persian festival shows a close resemblance to the Hindu *Holi* festival. In the Sacæa festival a bogus king rode naked through the crowd, over whom reddened water carried in pots was bespattered. In some of the villages of Bengal the practice still survives of dressing up a fool in a funny fashion and carrying him on a litter through the streets, while the crowd sing obscene songs and sprinkle one another with reddened water. The fool is called King of the *Holi* festival. In many districts an earthen *mañca* is erected with three graduated floors, on the topmost of which an idol of the presiding deity is seated for purposes of worship. This structure bears a close resemblance to the ziggurat. The *Holi* festival, it is noted, does not appear in the Vedic literature, and is evidently a feast of the people.

Transport of Tetanus Toxin to the Central Nervous System. Tetanus or 'lock jaw' is caused by the action of tetanus toxin upon the brain and spinal cord. A wound becomes infected with the tetanus bacillus, which there forms its poison or toxin, and when the toxin reaches the central nervous system, the spasms and convulsions characteristic of the disease result. In the past it has been held that the toxin is not conveyed by the blood or lymph, but by the nerves themselves, either by the nerve fibrils, by the neural lymphatics or by the nerve tissue spaces according to different hypotheses. These views are not accepted by Prof. John Abel in his presidential address to the American Association meeting at Boston in December last (*Science*, 79, 1934, pp. 63 and 121). He points out that there is no valid evidence that nerve fibrils convey toxin. Experiments with convulsant dye-stuffs show that these reach the brain by way of the circulating blood. As regards the neural lymphatics, recent anatomical studies show that these do not discharge into the cerebro-spinal fluid, but into the lymph glands of the general lymphatic system; nor does it seem possible that the tissue spaces of the nerves are capable of conducting the toxin. Prof. Abel concludes, therefore, that tetanus toxin reaches the central nervous system by the circulating blood. He also finds that, contrary to the old ideas, after an injection of toxin, the toxin does not quickly disappear, but considerable amounts persist in the blood and lymph up to the time of the death of the animal.

Crabs in Corals. The crab genus *Cryptochirus* consists of small crabs occupying pits in heads of living coral. There is no means of boring into the coral skeleton, therefore the pit is produced by the growth of the coral about the crab, which when young settles down in a calicle, causes the death of the polyp therein, and remains more or less passive while the living material is gradually laid down about it by the activity of the surrounding coral polyps. Dr. C. H. Edmondson (‘*Cryptochirus* of the Central Pacific”, *Bernice P. Bishop Museum, Occasional Papers*, 10, No. 5, 1933) describes four new species and gives notes on two others. One of these new species, *C. minutus*, is shown to have a peculiar zoea which has a close resemblance to that of *Haplocarcinus marsupialis*, Stimpson, inhabiting galls on many species of corals, an interesting fact which helps to clear up the question of the affinity of the two genera, about which there has been some discussion. *C. minutus* is a small species, the female with carapace only 3 mm. long, inhabiting pits in *Cyphastrea ocellina* and *Leptastrea purpurea*. Some of the pits concealing the females reach a depth of 12 mm. and many are curved or angular in their course. The males, about 1.5 mm. long, do not inhabit the pits with the females, but are found on the surface of the coral in shallow depressions or in a calicle in which the coral polyp has been destroyed

Systematic Position of Stromatoporoids In a paper on *Gypsina plana* and on the systematic position of the Stromatoporoids (*Quart J Micro Sci*, 76, Pt 3, Jan 1934) Prof S J Hickson states that the study of the collection of large specimens of this species made by Prof J Stanley Gardiner in the Indian Ocean suggested to him there was some relationship between these large Foraminifera and the ancient Stromatoporoids Recent investigation of specimens collected by Dr Crossland in Tahiti has confirmed his opinion and he has now no doubt that the Stromatoporoids were Foraminifera, a view that was held last century by W B Carpenter and others All the specimens from the Pacific and Indian Oceans, the Red Sea and the West Indies belong to the same variable species and thus may lead to a reconsideration of the validity of the specific distinction of many other sedentary Foraminifera Two small examples of *Gypsina* are described, they are thin flat discs, 0 6 and 0 9 mm in diameter respectively, and each exhibits a central chamber surrounded by a spiral of five or six chambers, and a thin crust of thin walled acervuline chambers It is suggested these may possibly be the microspheric forms, the large encrusting examples being the megalospheric forms A detailed description of the encrusting forms is given The systematic position of the Stromatoporoidea is fully discussed and the author points out that if the current view is maintained that the fossil forms referred to the Stromatoporoidea were Hydrozoa, then it follows that the Hydrozoa were in existence in Early Palæozoic times, but if as the author concludes they were allied to recent Foraminifera, then there is no clear evidence of the existence of Hydrozoa earlier than late tertiary times

Classification of the Poppy The cultivated poppy and the sesame have been the subjects of detailed investigations by the Institute of Plant Industry, U S S R In The Poppy (Supplement 56, *Bull App Bot*, *Gen and Plant Breeding* 1933, Institute of Plant Industry, Leningrad), Vesselovskaya offers a new classification of *Papaver somniferum*, L based on geographical and ecological principles The author also gives an interesting historical survey of the cultivation of the crop for both oil and opium, this, together with linguistic evidence, is used to support his hypothesis about the origin of the cultivated poppy The investigation is based on a collection of 1,600 samples of seed from various parts of Europe and Asia, all of which were sown in different stations in the U S S R The species falls into a series of seven individual geographical races, formed under the special climatic features of certain areas The parallelism of ecological types of the cultivated and dehiscent poppy indicate that the biological differences of form within the species are due to the prolonged action of various climatic conditions which occur over its area of distribution, stretching from the Atlantic to the Pacific, and from lat 61° N to India The author differs from Basilevskaya in attaching no value to the open or closed condition of the capsule for classification purposes, and in dividing the sub species into a greater number of varieties according to the colour of the flowers and the shape of capsule

Antirrhinum Rust Snapdragons have recently been observed to suffer from a rather severe rust disease Mr D E Green, mycologist to the Royal Horticultural Society, first noticed the trouble in the early summer of 1933, and has since found that many gardens are infected (Antirrhinum Rust, a Disease new to Great Britain, caused by the Fungus *Puccinia antirrhini*, Diet & Holw ' *J Roy Hort Soc*, 59, 119 Feb 1934) Symptoms of the disease are described—brown coloured pustules on the under sides of leaves—and the fungus is shown to produce uredospores and teleutospores The latter can germinate to form basidiospores but these cannot apparently infect snapdragon plants and no alternative host is yet known It is suggested that the fungus persists on plants kept through the winter, and produces uredospores when conditions are suitable Control has been effected in Canada and America by dusting infected plants with flowers of sulphur, whilst the temperature is maintained over 72° F at least twelve hours a day for three days

√**Protection of Stored Rice** According to a Mail Report issued by Science Service Washington D C a new method of protecting rice stored in bulk from insect attack has been tested by Dr E R de Ong consulting entomologist of the city of San Francisco Weevil injury to stored stocks of rice becomes very severe when the stores have to be carried through the summer until the late fall If unchecked, it may result finally in an almost complete destruction of the rice It has been found that coating rice with finely powdered calcium carbonate has given encouraging results under experimental conditions In a jar of uncoated rice, living rice weevils and bran bugs were introduced A similar number of these creatures were likewise placed in another jar to which one per cent of calcium carbonate had been added At the end of the year following the hot summer weather, the number of weevils in the coated rice remained stationary, that is, there had only been sufficient breeding to equal those which died In the uncoated rice the weevils had increased by more than one thousand per cent The weevil attack in the uncoated rice resulted in a loss in weight of 42 per cent—a cubic foot of the coated rice weighed 76 pounds, and the uncoated rice 44 pounds

Jurassic Cephalopods of Kachh (Cutch) The ' Revision of the Jurassic Cephalopod Fauna of Kachh (Cutch) by Dr L F Spath, which has been in course of publication since 1927, has now been completed (*Palæont Indica*, N S, 9, Mem 2, part 5, 1931, pp 551–658, pls 103–124, part 6, 1933, pp 659–945, pls 125–130) Although nominally a revision of the work of Waagen (1875) it deals with a vast amount of new material The author has examined more than 6,600 specimens, in which he recognises 23 species of belemnites, 12 of nautili and 521 of ammonites The deposits, which have an estimated thickness of more than 6,000 ft, range in age from Bathonian to Tithonian and show a general agreement with the stratigraphical succession in Europe The systematic part of the monograph, dealing with 556 species, may appal the stratigraphical geologist, but he will read with interest the concluding chapters on the analysis of the fauna, the palæontological conclusions, and the comparison of the fauna with those of similar age in all parts of the world The author rejects Buckman's view of the universal distribution of ammonite zones since, at the present day, no group of marine animals shows a world wide range, and moreover in the Kachh fauna at least 400 out of the 556 species are to be regarded as local in their distribution Waagen noticed the identity or resemblance of some species to those found in Europe especially in the Mediterranean region Further work, however, has considerably reduced the percentage of the species common to the two regions Unlike many palaeontologists, Dr Spath, after a prolonged and extensive study of ammonites, has come to the conclusion that the evidence of ontogeny is of very little value as an indication of phylogeny and may be altogether misleading Similarly, current views on orthogenesis find no favour in his eyes We also read (p 837) that faunal identity in different areas 'may indicate anything but contemporaneity" A summary of Spath's views on the evolution of the Cephalopoda has been given elsewhere (*Biol Rev* 7, 4, 418 1933)

A New Test for Large Mirrors In the April number of the *Observatory* appears a report of the meeting of the Royal Astronomical Society at which Prof Zernicke propounded the wave theory of Foucault's test and a new method of testing optical surfaces and Mr Burch described the practical application of Zernicke's method The method is extremely powerful, and errors in a mirror surface of the order of a tenth of a wave length of light show up very clearly An advantage of the new method is that the high and low areas of the imperfectly shaped mirror appear in different colours and it is much easier to decide which is a high and which a low area and polish accordingly It is impossible to do justice to the method in a few words, but briefly, it consists in illuminating the mirror with a pin hole source, and examining the image of this source through a tiny disc which retards the phase of the light by a fraction of a wave length Mr Burch makes these phase discs by pouring an acetone solution of resin into water and collecting the globules of resin which are precipitated These are then pressed into small discs between microscope slides The smallest discs are about 1/400 mm in diameter

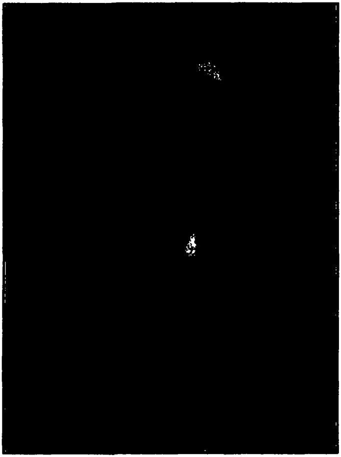
Copper Oxide Rectifiers in Ammeters and Voltmeters For the measurement of small alternating currents and voltages, the copper oxide rectifier used in conjunction with a moving coil instrument possesses far greater sensitivity than any other arrangement It is probable that this combination will be used extensively in the future Hence the paper read by Dr E Hughes to the Institution of Electrical Engineers on March 2 on the accuracy of these combinations is a timely one His tests show that the introduction of a rectifier into a circuit distorts the current wave and causes a rectifier-ammeter calibrated as usual with a sine wave to read low When used in conjunction with a current transformer, it is shown that the ratio of the primary to the secondary current may be rendered practically independent of the current frequency and wave form in two different ways One of these is simply to design the transformer so that the secondary winding has a very large self inductance A paper was also read by R S J Spilsbury in which he describes an instrument incorporating a copper oxide rectifier which gives the form factor of an alternating current wave by a direct reading The form factor, that is, the ratio of the effective value of a wave to its mean value, is of importance in several branches of electrotechnics For example, it is necessary to know this quantity before we can compute the voltage of an alternator or calculate the eddy current losses when testing transformer steels This instrument is being developed in the National Physical Laboratory

Wireless Reception in Naval Ships A paper read by Dr W F Rawlinson before the Wireless Section of the Institution of Electrical Engineers on March 7 discussed problems encountered in the reception of wireless signals in naval ships, and described certain features of the types of apparatus which have been developed for this application In a man of war, the choice of receiving aerials is limited, and it frequently becomes necessary to operate several receivers on different wave lengths from the same aerial Furthermore, in large ships the central receiving room is placed well down below armour, and the distance between the foot of the aerial and the receivers may be up to 100 ft The receivers themselves must be of robust design capable of withstanding the shock of gunfire and of working for years with a minimum of attention in a salt laden atmosphere at temperatures varying from tropical heat to arctic cold Three standard types of receiver were described in the paper, for short, medium and long waves, the total frequency range thus covered being 15-23,000 kilocycles per second These instruments must be capable of rapid tuning to any predetermined wave length, and they must be sufficiently selective to receive weak signals, which are invariably in Morse code, in the presence of a much more powerful signal on a different wave length transmitted either by the same or a nearby ship or by a shore station The concluding portion of the paper dealt with the question of power supply to receivers Common batteries are used to a large extent, but trials are being made with plant designed to take the supply from the ship's mains, special devices being incorporated to stabilise the output in the presence of considerable variation of the main's voltage

Testing Petroleum Stills A paper was read by A H Goodliffe on the practical testing of a continuous petroleum still before a joint meeting of the Institutions of Chemical Engineers and Petroleum Technologists on March 21 The paper gave a description of a plant on which experiments have been carried out, together with results obtained, and further included a detailed log of a particular run of the plant, there followed calculations on the plant and equipment and, finally, qualitative analyses of one of the distilling columns with special reference to the action of bubble trays in promoting fractionation The description of plant included an explanation of a flow diagram of the continuous still employing two towers of similar design, with further details of heating equipment duplex pumps for feeding the crude to the plant and automatic temperature control The log of the run of the plant set forth full details of a trial made last year both as regards specification of the crude, residue and product, which in this case was white spirit The most constructive part of the paper, however, was that dealing with calculations on plant and equipment, which provided much valuable information usually only available from internal reports of refineries No special apparatus was required to secure the necessary information for determining balances, performance and efficiencies beyond that in normal use in all refineries, and much of the testing apparatus used did not transgress the normal chemical requirements of all oil testing laboratories

Dr. Harlow Shapley

At the beginning of this year, Dr Harlow Shapley, director of the Harvard College Observatory and Paine professor of astronomy at Harvard since 1921, was awarded the Gold Medal of the Royal Astronomical Society for his studies of the structure and dimensions of the galactic system On May 11 he will deliver the George Darwin Lecture of the Society, taking as his subject "Some Structural Features of the Metagalaxy



Dr Harlow Shapley

Dr Shapley was on the staff of Mount Wilson Observatory from 1914 until 1921, and during that period probably his most important contributions were the photometric studies relating to stellar clusters An adaptation of the relation between the apparent brightness and the period of a Cepheid variable resulted in his determination of the now universally accepted 'period luminosity' curve, by the aid of which great celestial distances are derived

By means of this or an allied method, Dr Shapley found the globular clusters to be at distances from 20,000 to 200 000 light years, a conclusion which revolutionised previous conceptions of the size and arrangement of the stellar universe His many new ideas on various astronomical topics, especially variable stars, gave rise to pioneer investigations such as a study of spectral changes in Cepheids, whence came his 'pulsation theory' or periodic flow and ebb of heat' as the cause of such variation

In 1921, Dr Shapley was appointed Paine professor of astronomy at Harvard University and director of Harvard Observatory He at once began to plan and carry forward a large variety of celestial explorations, extending from the casual meteor caught in the earth's atmosphere to the remotest nebulous patch on the Bruce photographs of long exposure for metagalactic surveys His meteor project is apparently the first intensive professional attempt to study shooting stars systematically A careful examination of about 100,000 Harvard photographs yielded a total of only 550 trails Since many more meteors can be seen visually than are ever photographed, Dr Shapley organised, about two years ago, with the assistance of Dr E J Opik, an expert corps for the study of these objects, with observations in the clear Arizona sky and analysis at Tartu, Estonia About 26,000 meteors were seen An interesting first result is that only thirty per cent of the visual meteors are from the solar system, the fainter ones coming from interstellar space Therein lies a hope of additional knowledge concerning the great ocean of space around us

A few other subjects in the large observational programme at Harvard may be mentioned The Magellanic Clouds are being studied intensively by several members of the staff, and have already yielded numerous super giants, new peculiar spectra, clusters and variables The programme for systematic examination of the Milky Way in 196 selected regions has already resulted in the discovery of twenty five hundred new variables and the determination of many periods

The problem of the extra galactic nebulæ is now progressing steadily The publication in 1932 of a catalogue giving the positions and photographic magnitudes of all extra galactic nebulæ brighter than the magnitude 13 0, left the way clear for observational work on the second survey reaching to the eighteenth magnitude and to the distance of about a hundred million light years The number already found on the Harvard plates exceeds one hundred thousand, and five hundred or more are often revealed by the examination of a single photograph

The long established practice of the Harvard Observatory in being a collector of facts has thus been continued by Dr Shapley in many lines of research The theoretical side is also being stressed; for example, discussions of orbits, statistical studies of star distribution, and researches upon the origin of spectral lines and on the universal abundance of elements

Dr Shapley's activities are, however, by no means limited to observatory tasks All human problems interest him and his versatility is illustrated by helpfulness in various educational problems it may be counselling non scientific faculties of several colleges as to advantageous research problems or perchance advising the Board of Trade of a textile city during the present collapse of industrial values as to the most judicious expenditures for educational purposes

It is not generally known that Dr Shapley's most interesting recreation is the study of ants For two years on Mount Wilson he observed and studied the habits of trail running ants seventy thousand of them on some summer days going along each file Under varying atmospheric conditions he measured their speed at fixed intervals of distance The fact was established that their speed is a function of temperature alone and increases fifteen fold with an increase of 30° C in air temperature Conversely a single observation of the ant speed led to the prediction of the temperature within 1° C Thus to his period luminosity and spectrum period relations among the stars he added the speed temperature relation among ants Descriptions of some of these observations will be found in the paper Thermo kinetics of *Liometopum apiculatum* Mayr published in the *Proceedings of the National Academy of Sciences* for April 1920 Dr Shapley has also studied the morphology of ants as evidenced by his large collection of worker ants with wing vestiges described in a Note on Pterergates in the Californian Harvester Ant (*Psyche* 27 No 4)

Perhaps his study of ants taught Dr Shapley not only speed but also conservation of energy for with all his other activities he has found time to compile the Source Book in Astronomy and to write books such as Star Clusters and five chapters in the Universe of Stars a pioneer series of radio talks given in 1925 by members of the Observatory staff As a lecturer either at universities or before the general public he is very successful Why this is so may be readily understood by reading his small books Sidereal Explorations and Flights from Chaos based on lectures given at the Rice Institute of Texas and the University of the City of New York

Scientific Research in Relation to Patents in the United States*

SINCE the War scientists have been called upon by industry in increasing numbers for assistance in overcoming technical difficulties involving such problems as improving old products or processes or devising entirely new products This dependency of industry upon science has been particularly marked in the chemical and electrical fields where large industrial research laboratories have been established for investigating all phases of the products of their respective organisations From their original task of mere laboratory control of the manufactured products these industrial laboratories have extended their sphere of activity to such a large extent as to include research in the fundamental sciences Industrial leaders have come to realise that fundamental research may be of vital importance to industry for it may revolutionise existing practices or create new ones in the most unexpected quarters

PATENTABLE INVENTIONS OTHER THAN MEDICAL

These increasing contacts of scientists with the problems of industry have brought to the fore the difficult problem of adequate remuneration for their services, as well as the problem of giving the public the effective benefit of their work In many cases valuable solutions have been made to difficulties which were patentable Scientists have also begun to realise that many of the fruits of their research have valuable industrial applications which can be patented The troublesome questions thus arise Should they proceed to obtain patents ? What are the advantages in doing this ? What are the disadvantages ? A good deal of discussion has already occurred on these questions but no definite policy has yet been formulated The investigator who takes advantage of our patent laws is perfectly warranted in his act not only for any possible financial returns but also for the good of the public The obtaining of some remuneration from a patent is no more debasing or tainted with commercialism than the acceptance of copyright royalties from a text book or even receiving a salary for teaching We are at present living in an economic structure in which the making of legitimate profit is a fundamental assumption

There are many advantages in securing patents for important advances as only by means of patents can the legal right be secured to exclude others from practising a given process or commercialising a new product By having such control of new discoveries the investigator is assured that his results will be used only for proper and meritorious purposes He can prevent the exploitation of the public by dictating the terms under which his patent should be worked and even control the character of the commercial advertising

MEDICAL PATENTS

The committee recognises the fact that there exists in many quarters a strong feeling against medical patents This feeling seems to be largely due to the unpleasant memories of the past exploitation of the public by means of patent medicines which had doubtful or decidedly harmful effects on the public health Government regulation during recent years has eliminated a great deal of misrepresentation and false claims in regard to this class of goods The Patent Office moreover now seldom issues patents for the old fashioned type of patent medicines It is therefore an error to class all medical patents with the former types of patent medicines

The mere fact that medical patents offer the means of making profits is not a sufficient reason to condemn them entirely It must be remembered that patents have other very important uses Moreover we must bear in mind that it is possible to obtain profits from medical discoveries in many other ways without resorting to patents if the medical investigator is so inclined We must after all depend upon the integrity and character of the investigator when important medical discoveries are involved

The ideal to strive for may perhaps be that no medical discoveries should be subject to any restrictions whatsoever In our present commercial economic system, however, and with existing laws and business practices, such an ideal is difficult to attain, since not all may live up to it We must, therefore, guide ourselves in accordance with the economic situation that exists to-day and seek to attain our ideals through the existing economic machinery rather than to ignore it entirely on the ground of ethical consideration alone

---

* From 'The Protection by Patents of Scientific Discoveries , being the Report of the Committee on Patents Copyrights and Trade Marks Joseph Rossman (Chairman), F G Cottrell, A W Hull and A F Woods. Occasional Publications of the American Association for the Advancement of Science No 1 January, 1934 Supplement to *Science*, vol. 79 (New York The Science Press.) 50 cents

The act of securing patents for medical discoveries is not unethical in itself, and such act does not necessarily mean that personal profits are sought Under our existing laws and commercial practices dedication to the public of important medical discoveries by mere publication is not always the best procedure to follow The public can often be best served by receiving the benefits of a new medical discovery under the control of a patent Through making a medical discovery it may become the duty of the investigator to make sure by means of patents that the public will actually benefit from his discovery and not be subjected to unfair exploitation by others who may commercialise his discovery

NON PATENTABLE SCIENTIFIC DISCOVERIES

The proposal that the discoveries of scientists be given some legal protection appears on its face to be very reasonable and plausible It would seem that scientists should be the first to desire such rights as a means of receiving compensation for their contributions to industry and society A careful analysis of the whole problem, however, has led the committee to the opinion that no effort should at present be made to develop a plan for protecting scientific property There appears to be no need for such legal protection from the view point of incentive to the scientist or public policy The Committee recognises that the present economic crisis has tremendously diminished the normally available funds for carrying on research so that other sources of potential funds are to be carefully considered at this time It believes, however, that the legal and practical difficulties involved in enforcing any scientific property would eventually arouse an unfavourable public opinion against scientists, owing to the difficulty of enforcing scientific property and the inherent nature of its broad monopoly The results of irksome scientific monopolies would react to the disadvantage of scientists and thus defeat the very purpose for which this proposal is made

---

University and Educational Intelligence

CAMBRIDGE —The Jane Ellen Harrison Memorial Lecture will be given on May 5 at 5 p.m in the College Hall, Newnham College, by Dr L S B Leakey, of St John's College The subject of the lecture will be 'The Problem of the Origin of Man'

Prof Buxton has been appointed to represent the University at the Twelfth International Veterinary Congress to be held in New York in August

SCHOOL libraries in the United States are credited with having contributed in no small measure to the improvement in efficiency which has taken place in the schools in the last three decades According to the Dean of the Graduate Library School of the University of Chicago, Dr L R Wilson, whose views on increasing the significance of the school library are published in *School and Society* of December 30, the once prevalent use of the single textbook recitation procedure has been superseded by a method of instruction by which many books and materials are studied Although his theme is the development and fuller utilisation of the school library, his argument implies that its functions are already of great importance He refers, for example to the librarian's "responsibility of co-ordination and generalship in the field of supervised study" and to the library being the principal integrating agency of the entire school' He mentions as deserving imitation the present effort on the part of the librarians of colleges and secondary schools in the Southern States to work out a co-operative plan for supplying school library facilities in rural areas He advocates the provision, in library schools or teachers colleges, of training for the part time teacher librarian in small schools, and the investigation of a number of problems relating to the school library which, he says, have as yet been only slightly considered These he proceeds to discuss under the headings administration, teaching the use of books in libraries standards for school library service, distribution of library resources, measurement of school library influences During the past twelve months the *Journal of Education (London)* has published a series of articles, by specialists in various subjects, on the library requirements of secondary and public schools in Great Britain

TENDENCIES in university education are discussed in the John Adams lecture given in the Institute of Education, University of London, on October 10 by Dr E Deller, principal of the University (London Oxford University Press 1s) Dr Deller examines some of the implications of the growth in number of students which has marked the recent history of so many universities He discerns a danger of over mechanisation, and a menace to academic freedom University administration is susceptible of hypertrophy, as in those Russian institutions where the head is a director, responsible in the same way as the controller of a factory Extensive student enrolment has led in Germany, where the number of unemployed graduates has been estimated to be 90,000, to other perils "The university is to-day a temporary haven of refuge," said Prof Dibelius recently, "for innumerable individuals who otherwise as soon as their school years were over, would sink to the ranks of the proletariat what a dangerous mass of inflammatory, revolutionary material and social embitterment are heaping themselves up now in those old homes of German culture " The number of students in England is not as yet, Dr Deller thinks, excessive, but he holds that the line of advance for the future must be qualitative rather than quantitative How views as to the proper functions of a university increasingly diverge he shows by quoting from "The University in a Changing World": in Russia and Italy, and more recently in Germany also, the view prevails that all learning must be related to the dominant political creed He suggests that universities can best help forward the rehabilitation of a distressful world by ascertaining truth rather than by attempting the adjustments and compromises, which are the proper task of the statesman, and also by extra mural teaching

Science News a Century Ago

Anode and Cathode

Faraday, when he read his Seventh Series of Experimental Researches in Electricity" before the Royal Society in January 1834, made use of a number of new words in describing the electro chemical phenomena with which the Series is concerned When, later in the year, the paper appeared in print, some of these terms had been changed, and a footnote added in which it was explained that the alterations had been made in order that the new words should be only such as were at the same time simple in their nature, clear in their reference, and free from hypothesis" In the interval Faraday had been in correspondence with friends, and the discussion *produced that series of terms, essential to electro chemistry*, which has since passed into common usage One of his correspondents was W Whewell, afterwards Master of Trinity College, Cambridge, who wrote on May 6

I still think *anode* and *cathode* the best terms beyond comparison for the two electrodes The terms which you mention in your last shew that you are come to the conviction that the essential thing *is to express a difference* and nothing more This conviction is nearly correct, but I think one may say that it is very desirable in this case to express an opposition, a contrariety, as well as a difference The terms you suggest are objectionable in not doing this They are also objectionable, it appears to me, in putting forward too ostentatiously the arbitrary nature of the difference To talk of Alphode and Betode would give some persons the idea that you thought it absurd to pursue the philosophy of the difference of the two results, and at any rate would be thought affected by some Voltode and Galvanode labour no less under the disadvantage of being not only entirely, but ostentatiously arbitrary, with two additional disadvantages, first that it will be very difficult for anybody to recollect which is which, and next that I think you are not quite secure that further investigations may not point out some historical incongruity in this reference to Volta and Galvani I am more and more convinced that *anode* and *cathode* are the right words"

The letter, which is preserved at the Royal Institution, is reproduced in Facsimile in "Faraday's Diary", vol 2

Mural Circle for Edinburgh Observatory

On May 6, 1834, at a meeting of the Institution of Civil Engineers, Mr Simms gave an account of the six foot mural circle just completed for Edinburgh Observatory The instrument, he said, differed in no important respects from those at Greenwich His paper contained a valuable review of the art of dividing instruments Mr Simms said that about the middle of the eighteenth century, Mr Hindley, a clockmaker of York, introduced several important improvements He gave motion to the plate of a tangent screw, invented a frame for carrying a point, in place of using a knife against the fiducial edge of a ruler, and also introduced the elliptical cutting point The Duc de Chaulnes was the first who made use of double microscope micrometers in dividing Ramsden's dividing engine, for which he was rewarded by the Board of Longitude, appeared in 1775 He adopted Hindley's inventions of the endless screw, the cutting frame and the elliptical point, but his machine abounded in beautiful and ingenious contrivances Many dividing engines had been made in Great Britain, by Dollond, Stancliffe, John and Edward Troughton, and abroad by Reichenbach and Gambey For the Edinburgh circle the divisions were cut on a band of gold inlaid on the circumference and the degrees were engraved upon a band of palladium slightly alloyed with silver

Lyell on the Loess Deposits

At a meeting of the Geological Society held on May 7, 1834, Lyell read a paper on the Loamy Deposit called Loess in the Valley of the Rhine', in which he described his investigations made in *1833* between Cologne and Heidelberg and in other districts From his examination of the shells contained in the loess at various places and a study of the land and aquatic shells obtained from the banks of the Rhine, he concluded that (1) the loess was the same material as the sediment with which the waters of the Rhine were charged, (2) the fossil shells in the loess were all of recent species, (3) the number of individuals belonging to land species usually predominated over the aquatic, (4) although the loess when pure appears unstratified it must *have been formed gradually*, (5) some volcanic eruptions must have taken place during and after the deposition of the loess The deposits of loess between Heidelberg and Heilbronn, he said, appeared to attain a height of seven or eight hundred feet above sea level

Darwin in Patagonia

About a month before H M S *Beagle* passed through the Straits of Magellan into the Pacific and while the ship was still in the mouth of the Santa Cruz, Darwin recorded in his Diary on May 9 11, 1834 I took some long walks, collecting for the last time on the sterile plains of the Eastern side of S America ' He also wrote The sportsmen have altogether been very lucky Ten guanaco have been killed and eaten, several condors and a large wild Cat have been killed and Mr Stuart shot a very large Puma" These various creatures were fully described in his Journal of Researches", and of the guanaco he said "The guanaco, or wild Llama, is the characteristic quadruped of the Plains of Patagonia, it is the South American representative of the camel of the East It is an elegant animal in a state of nature, with a long slender neck and fine legs The guanacos appear to have favourite spots for lying down to die On the banks of the St Cruz, in certain circumscribed spaces, which were generally bushy and all near the river, the ground was actually white with bones On one such spot I counted between ten and twenty heads I particularly examined the bones, they did not appear as some scattered ones which I had seen, gnawed or broken, as if dragged together by beasts of prey The animals in most cases must have crawled, before dying, beneath and amongst the bushes Mr Bynoe informs me that during a former voyage he observed the same circumstance on the banks of the Rio Gallegos I do not at all understand the reason of this, but I may observe, that the wounded guanacos at the St Cruz invariably walked towards the river"

Societies and Academies

London

Royal Society, April 26 F W P Götz, A R Meetham and G M B Dobson Vertical distribution of ozone in the atmosphere A method has been developed for finding the average height of the ozone in the earth s atmosphere and also the general character of its vertical distribution This method uses spectroscopic measurements of the light of the clear blue zenith sky as the sun is rising or setting The necessary observations have been taken in Switzerland over the space of a year and the height and vertical distribution have been calculated The average height is found to be about 22 km above sea level and most of the ozone exists between the ground level and 40 km The vertical distribution depends on the total amount of ozone present but apparently not greatly on other factors F P Bowden and C P Snow Physico chemical studies of complex organic molecules (1) A method is described for the production of monochromatic light of sufficient intensity to bring about reasonably rapid photochemical changes The irradiation can be performed on very small amounts of material and the progress of the reaction followed spectroscopically Selective monochromatic irradiation is applied to some of the large molecules of biological importance notably ergosterol and calciferol vitamin B, carotene and vitamin A F P Bowden and S D D Morris Physico chemical studies of complex organic molecules (2) The absorption spectra of some important biological molecules have been measured at liquid air temperature The bands of β carotene (in ethyl alcohol) become narrower and shift to 4990 A 4670 A and 4350 A and a new band appears at 4060 A The ultra violet band at 2700 A becomes sharper but is little displaced The main band of vitamin A concentrates at 3280 A is shifted to 3350 A and new structured bands appear at 2900 A 2770 A 2580 A 2510 A and 2430 A The absorption spectrum of vitamin E concentrates is due to several different molecules and some progress has been made in separating these out

Dublin

Royal Dublin Society, January 23 T N Richardson and K C Bailey The oxidation of hydrazine by potassium ferricyanide When this reaction takes place in alkaline solution supersaturation by nitrogen gas takes place so readily that the reaction can only be followed by the rate of evolution of gas if stirring is very efficient Acetone retards the reaction by formation of dimethylketazine which is not oxidised under the conditions of the reaction Robert McKay Injury to apple trees due to mineral oils used for the control of woolly aphis A canker on maiden apple trees originating in a nursery in the south of Ireland was traced to the use of paraffin oil for the control of woolly aphis Various types of injury produced by paraffin on apple trees of different ages and varieties are described, the injury being aggravated by the presence of woolly aphis Paraffin oil or petrol should not be used alone on apple trees at any season

Paris

Science and Intellectual Liberty

A LITTLE more than a year ago a number of scientific workers and scholars formed themselves into an Academic Assistance Council with the intention of helping university teachers and investigators who on grounds of religion political opinion or race were unable to carry on their work in their own country The Council consists of forty two members representative of all sides of British intellectual activity and its first annual report which has just been issued is a document worthy of careful study* Upon the Council s records are the names of 1 202 scholars and scientific workers who have been displaced Of these rather more than a quarter 389 have been permanently or temporarily—in the majority of instances only temporarily—enabled to continue their work 178 in the British Isles 211 abroad There remain 813 so far unsuccoured

Although the Council does not confine its aid to those of German origin nearly all these distressed intellectuals have come from or still suffer in Germany It might seem then that the Germany of to day is not a very kindly soil for the cultivation of science and scholarship Prof J Stark president of the Physikalisch Technische Reichsanstalt Berlin has however been at some pains to demonstrate both in our correspondence columns and also in a pamphlet entitled National sozialismus und Wissenschaft † that far from seeking to diminish scientific freedom it is the mission of the National Socialist Government to free German science from the influences which were strangling it

It is necessary first of all to realise the distinction in the German political mind at the present time between *Germanen* and *Juden* To *Germanen* has been vouchsafed the gift of seeing things as they really are with the result that practically all *Naturwissenschaft* is regarded as the creation of the Nordic German branch of the Aryan peoples The *Juden* on the other hand are entirely centred on themselves cannot or rather will not see things as they really are and only respect facts which can be made subservient to their own ends They are consequently quite incapable of making any great discoveries in *Naturwissenschaft* It is true that Heinrich Hertz made an important discovery but then Hertz had a Germanic mother

---

* The Academic Assistance Council Annual Report, 1st May 1934 (London c o Royal Society, Burlington House, London W 1)

† Zentralverlag der N S D A P München 1934

We might also mention names, such as those of Jakob Henle and Paul Ehrlich , whether anatomy and immunology are not *Naturwissenschaften* at all, or the pedigrees of Henle and Ehrlich have been insufficiently scrutinised, we do not know The result of the moral and intellectual limitations of the *Juden* has been, not only that they have devoted themselves to unreal theorising, but also that little Jewish coteries have succeeded in strangling genuine German science One of these *judische Wissenschafter Konzerne* founded by Klein and Hilbert no doubt discouraged that stern objectivity which should characterise Nordic German mathematics , another, controlled by Einstein and Sommerfeld, tampered with physics a third, the Haber *Konzern*, has strangled physical chemistry What *Konzern* has suppressed Germanic biology is not disclosed Anyhow, we are apparently led to the conclusion that, instead of discovering anything important, Germany has been simply putting on the market dogmatic theories, such as Einstein's theory of relativity

It may be difficult for the English reader, recalling the often painful elaboration of genuine Germanic humour, not to suppose that Nationalsozialismus und Wissenschaft' is a facetious essay, but the consequences of its acceptance in Germany are too plainly evident No one can suppose however, that this kind of reasoning' will be taken seriously long Even the Committee of Public Safety was not wholly composed of Barères more temperate counsels will prevail in Germany in good time Meanwhile, however, a good deal of 'sand' is being thrown into the intellectual machinery of the world

One function of the Academic Assistance Council has been to enable serious workers to escape from an atmosphere of noise and truculence and to continue their researches The reports of what has already been done by grantees show the success of the policy One (a mathematician) has finished an exceptional piece of work which will make a considerable sensation when it appears and add greatly to his status ' Another (a physiologist) has done work which, the referee thinks, "may well be revolutionary ' Another (an art historian) ' has been doing quite invaluable work" , and so the story goes on

These are the products of a single year's work and of comparatively trifling expenditure Were we only concerned for the credit of Great Britain and the enrichment of its intellectual life, we might almost pray that the present vogue in Germany would be long It would be difficult indeed to invest capital at a more usurous rate of interest—we are securing some of the best intellects in Europe, perhaps permanently However we all hope that the restraint of German intellectual activity will not continue , but common prudence must warn us that, for some years to come, much of the burden of maintaining the intellectual life of Europe will have to be borne by us The Academic Assistance Council estimates that £25,000 a year for the next two years will be necessary to enable it to continue and consolidate its work In 1931–32, according to the return of the University Grants Committee, the expenditure in Great Britain on salaries (including payments for superannuation) of teaching staff in university institutions of Great Britain was £2,856,216 The annual sum required by the Academic Assistance Council is less than one per cent of this While it would be preposterous to suggest that the whole of the burden can be, or should be, borne by the academic staffs of British universities, and reasonable to expect that enlightened men of wealth will contribute to this deserving object, it does at least appear that the Council is not asking for a sum beyond the means of those who value science and scholarship to supply

We doubt whether an appeal more worthy of support than this has ever been made to the educated public We have the ordinary appeal to decent human sympathy which the story of oppression makes, but beyond that is the appeal to our imagination The individuals suffering at present will pass away and be forgotten the revocation of academic freedom in Germany will no more be forgotten than the revocation of the Edict of Nantes

A Poet Looks at Religion and Science

The Unknown God By Alfred Noyes Pp 383 (London Sheed and Ward, 1934) *7s 6d* net

MR ALFRED NOYES is one of a not inconsiderable number of literary intellectuals who, having begun thirty or forty years ago as agnostics, have become in their maturity orthodox and practising Catholics This spectacle of agnostic poets leaving the waste land and returning *ad limina* is a sign of the times Now that the traditional European culture, which was predominantly literary, is in danger of being displaced by a new scientific culture with its strange products, human and material, the poet may experience a very natural distaste. He sees, or thinks he sees, the world being rapidly decivilised by the mass barbarian, who is a deplorable by-product of scientific developments. He is appalled by the prevalent vulgarity and insensitiveness to the values he cherishes, and repudiates modernity; and who shall say that he is altogether wrong? Compare the shallow philosophy, or philosophies (since there is a Babel of conflicting tongues) of modernity with the *philosophia perennis* of traditional Catholicism—with its richness, its comprehensiveness, its sweep and power of speculation, its nobility and depth of emotional content, and its rationality.

Yet this is not the sort of argument that Mr. Noyes proffers in his book. Out of disgust for the contemporary world he does not repudiate science which has created that world. On the contrary, he begins from the scientific point of view as found in T. H. Huxley, Herbert Spencer and Haeckel. From studying these writers in his youth, Mr. Noyes gained too clear an insight into scientific culture ever to wish to repudiate it out of disgust at a few of its products. Yet his interests in those early days were evidently philosophic rather than strictly scientific. What fascinated him were the perennial problems of space, of time, of personal identity, and so forth.

Yet the Victorian agnostics contained more than a little of the old culture suspended in their thought. "It was not really difficult for Mr. Noyes to discover parallel doctrines, a little differently phrased but not dissimilar in content, in Herbert Spencer and Aquinas. The modern unbeliever is at once more technical (though less verbose) and more tough than the author of the 'Synthetic Philosophy'." This indeed, is part of the trouble to-day. "Our men of science are all specialists, each working along his own narrowing line, each developing a language of his own, and each diverging further and further from that central point of view which once enabled us (from the lost height of a great historic religion) to 'see life steadily and see it whole'."

That is bad enough, though one does not see how it can be avoided. What is far worse is that the philosophers are specialists too. "We get very little that is helpful in constructing a satisfactory synthesis from modern metaphysicians, whose treatises are arid and technical; and if we turn to the poets and artists, they too let us down. Mr. Noyes is a poet himself and should know, and he tells us that art and literature are suffering from the same disease as science itself, in an aggravated form. Their exponents, with few exceptions, have no belief in real values. They are giving over to analysis what was meant for synthesis; and where they should be creative, or interpretative of life in its fulness, they offer us critical dissections and the disintegrated relics of a post mortem. More than ever before they mistake those superficial factual reports for truth; and, if the 'facts' are repulsive enough, they are inclined to suggest that truth requires no further evidence. It is not only the 'facts' of religion that are failing us."

Of course an apologist for the new literature would reply that the industrious and disinterested collection of facts must be preliminary to a synthesis; the task may be extremely unpleasant and even unpromising, but one has to proceed on the inductive principle. Perhaps we shall get our synoptic view in due course, but meanwhile modern writers will not look back for their interpretations and their ideals. They have certainly chosen the more difficult task. To resuscitate the past only calls for erudition and the sympathetic understanding of other people's ideas—in a word, for intelligence. But to provide something new (which is what the times call for), needs genuine creative power, and we may admit that not all our modern writers possess it.

If this is true in art and literature, it is more true than ever in the sphere of religion. As Mr. Noyes most justly says, the need of the world to-day is a religious need, but it is extremely doubtful whether this can now be satisfied by the orthodoxies of the past, however attractive they may be in themselves, however intellectually coherent they may be if you grant their premises, and however much by their grandeur they may expose our modern spiritual penury. "The world is groping," says Mr. Noyes, "for a religion in which it can believe without evasions, without dishonest ambiguities, without self-deception, and without superstition." That is just the point. A religion, however satisfying in other directions, is no good to you unless you can believe it with your whole heart. That Mr. Noyes finds traditional Catholic orthodoxy completely satisfying himself is evident from this utterly sincere and large-hearted book. But not all of us are so fortunate.

J. C. HARDWICK.

Advancing Sterility in Plants

Publications of the Hartley Botanical Laboratories Nos 1, 2, 4, 6, 7 *Studies in Advancing Sterility,* Parts I to V By John McLean Thompson No 11 *The Theory of Scitaminean Flowering* By John McLean Thompson No 3 *The Life History and Cytology of Sphacelaria Bipinnata* By Hilda B Clint No 5 *The Cytology of Callithamnion Brachiatum* By William T Matthias No 9 *A Contribution to Knowledge of the Mesogloiaceae* etc By Mary Parke Nos 8, 10 *Studies of Flowering in Heterostyled and Allied Species,* Parts I and II By James Stirling (Liverpool University Press of Liverpool 1924–1933)

THESE publications of the Hartley Botanical Laboratories of the University of Liverpool are beautifully printed and illustrated on large pages of good paper In them Prof McLean Thompson records his observations of floral development in a few selected families, and supports his view that only through such developmental studies is it possible to interpret floral form and structure satisfactorily In selecting the families for study Prof Thompson has shown himself ready to face difficulties His choice has fallen first on the Leguminosæ, one of the largest families of Dicotyledons, the very variable subfamilies Cæsalpinioideæ and Mimosoideæ having been investigated in considerable detail but the more uniform Papilionatæ much less extensively Next he has chosen the Lecythidaceæ and the Scitamineæ, two groups in which the flowers exhibit a wide range of freakish forms with marked variation in the number of functional stamens

The investigations of the Leguminosæ have been directed towards three main ends first, to find the directions of evolution within the family secondly, to interpret the morphology of the corolla and gynæcium, and thirdly, to reconstruct a prototype It was unfortunate that the Cæsalpinioideæ should have been studied before the Mimosoideæ, since the latter are certainly the more primitive in many respects, and conclusions derived from the former have had to be revised The final conclusions are that evolution has been mainly a progressive reduction in the number of stamens, with the ultimate attainment of monandry and apetalous dicliny The corolla is a secondary intercalation between perianth and androecium, and the legume is the reduction limit from a terminal system of phylloclades with marginal ovules The prototype showed numerous members in a continuous spiral sequence, bracteoles and perianth outermost, then stamens, and finally, on the apex of the long conical receptacle, the gynæcium

For the most part these conclusions seem incontrovertible The constancy of the serial origin of members even in apparently cyclic types is a point of considerable interest This has been observed also in Ranunculaceæ, and an essentially similar picture to Prof Thompson's has been drawn for that family The corolla has been regarded as arising secondarily, and all members as originally arranged in a continuous spiral sequence In both groups the members, as their numbers are reduced, settle down usually to pentamerous, but occasionally to trimerous or tetramerous, alternating whorls The derivation of such cyclic or pseudocyclic arrangements from the spiral offers no great difficulties if it be realised that the average angle of divergence between successive members in spiral types is never far removed from 137 5°, and that an average divergence of 144°, corresponding to the 2/5 phyllotaxy of the old Schimper Braun theory is rarely found Thus members cannot be supposed to have lain along a small Fibonacci number of radii, five eight or thirteen, and Prof Thompson had no need to assume and explain secondary displacements of 36° to remove a sixth member from radial juxtaposition to a first

There is no doubt that the numerous stamens of the prototype have been steadily reduced until, in several species, only one remains This does excuse the frequent use of such expressions as ' doomed", 'menaced by sterility", "await extinction" Much more must be known of the general biology of these types, of their pollination mechanisms and their ecology, however, before drawing a conclusion of suicidal orthogenesis

The evolutionary history of the legume is a much disputed matter Many might agree that the facts of form and vascularity do not support a multi carpellary interpretation It is not difficult to agree that the carpel, growing for the most part by intercalary elongation *after* infolding, is no longer a leaf whatever its form in ancestral types But to call it, with Prof Thompson, a phylloclade, does not seem to help appreciably In the first place there seems no strong reason, on grounds of structure and development, for calling it phylloclade rather than leaf, and in the second place it is far from evident why the organs figured in the reconstruction of the prototype should be called phylloclades rather than leaves There is sore need for a revision of morphological terminology

His studies of the floral development of the Scitamineæ have led Prof Thompson to deny the cymose nature of the peculiar partial inflorescences of such genera as *Musa* He adduces many interesting facts and submits an ingenious interpretation, but it cannot be said that his arguments are entirely convincing The frequent association in pairs of one left handed and one right handed flower is not satisfactorily explained in terms of the direction of movement of nutrient materials but is to be expected in a reduced cymose inflorescence

From a study of individual floral development emerges the fact that again in the Scitamineæ the members arise serially But the most interesting conclusion is that the gynæcium is not composed of carpels but of ovules arising on the walls of a receptacle crater which is roofed in by stylar components The inference is that the Scitamineæ are acarpous' in ancestry This does not seem a legitimate inference The inferior ovary is surely a derivative type in which the ancestral carpels have ceased to bear the ovules and are represented only by the 'stylar components' All stages between this and the hypogynous condition are known and the essential change seems to be in the distribution of growth after initiation of the carpels on a concave receptacle Growth of the carpels as free or concrescent members, independently of the receptacle, gives the superior ovary, but growth predominantly beneath the primordia, increasing the concavity of the receptacle or forming the loculi as pockets beneath the stem apex, gives the inferior ovary It is thus true that the ovary is not composed of carpels, but it cannot be maintained that it is ancestrally acarpous

Observations on the Lecythidaceæ reveal an interesting correlation between cell gigantism and sterility, and progressive sterilisation of the androecium is again recognised as the main evolutionary trend

The publications constitute a valuable collection of data on floral development, and Prof Thompson is to be congratulated on having directed attention to many outstanding problems for the solution of which his mode of approach may justly be claimed indispensable In conclusion it should be said that the drawings of flowers are extremely good, but perspective drawings and longitudinal sections should have supplemented the contoured plans and serial transverse sections in illustrating floral development Why should none of the floral diagrams be orientated in the conventional manner, and why should the inflorescence axis be represented by a little maltese cross or a more elaborate figure ? The large number of unfortunate printing errors of the earlier volumes has been much reduced in later volumes

Publications by other members of Prof Thompson's department deal with the development of heterostyled flowers (Nos 8 and 10), and with the life histories of certain algæ (Nos 3 4, 5 and 9) There are also valuable notes by Mr W Horton dealing with technical points

A R CLAPHAM

World Petroleum Congress

World Petroleum Congress organised by the Institution of Petroleum Technologists held at the Imperial College of Science and Technology, South Kensington London July 19th–25th, 1933 Proceedings Edited by Dr A E Dunstan and George Sell Vol 1 *Geological and Production Sections* Pp xxiv+592 Vol 2 *Refining, Chemical and Testing Section* Pp xxvi+956 (London World Petroleum Congress, 1934) Vol 1 35*s* net to Members of the Congress, 30*s* net Vol 2 45*s* net to Members of the Congress, 37*s* 6*d* net

IT is impossible accurately to assess the value or measure the success of the World Petroleum Congress, held in London on July 19–25 last, for, as with all international meetings of this character, vital problems discussed cannot be solved at the time, but must be referred to various committees of experts Only time and with it much detailed work, can show which of the innumerable ideas propounded at this Congress are of scientific import , many as yet must be classed as interesting but unproved theories Anyone, however, can furnish himself with at least one tangible and lasting memento of this international pooling of current ideas and can extract therefrom such technical information as may be necessary to his particular branch of research or industry The memento is a complete record of proceedings published at the offices of the Congress in two volumes Vol 1 includes all papers submitted in connexion with the Geological and Production Sections Each section and sub section is prefaced by a general reporter s summary giving the trend of present day thought and research at a glance

Geologists throughout the world are bringing the resources of science to bear on vexed problems of petroleum source rocks their geographical limits and the principles governing distribution of oil fields Geophysical science has advanced rapidly during the last ten years and papers on this subject provide an excellent basis of assessment of capabilities and relative usefulness of the numerous instruments now available The value of aeroplane reconnaissance and photography appears to be capable of enhancement and an urgency is obviously felt by its sponsors and operators for its more universal application to cover the vast amount of pioneer work still to be done Stress is also laid on analysis and interpretation of oil well data acquired during drilling—now a very exact science—and on the great assistance which such data though not always appreciated provide to field operators Drilling production transport and storage of oil form the main themes in the Production Section In the first instance opinions are collected and problems discussed chiefly in connexion with pressure drilling use of mud fluids and oil well cementation The second group comprises contributions describing actual production methods as now practised and their relation to reservoir conditions while the last group is of interest mainly from the point of view of modern pipeline construction and protection

Vol 2 contains a great deal more subject matter and includes papers on cracked gasoline refining and the use of inhibitors for gum prevention determination of gum in gasoline knock rating for motors and aviation gasoline fuels for high speed compression ignition engines hydrogenation extraction processes for the refining of oil lubricating oil viscosity bituminous materials and emulsions kerosene alternative fuels oil coal fuels petroleum as a chemical raw material and measurement of oil in bulk Two important considerations concern nomenclature from the legal aspect and international co operation in standardisation

Both volumes conclude with an account of the formal adoption of resolutions Sir John Cadman s lecture on Science in the Petroleum Industry and also Mr J B Aug Kessler s paper on Rationalization of the Oil Industry reports of which duly appeared in NATURE There are author and subject indexes at the end of each volume which in the latter case might with advantage have been made fuller in view of the technical value of these volumes as standard works of reference

The editing of such a large number of papers dealing with so many different subjects and presented in such diverse ways was however nothing short of a Herculean task and the editors are to be congratulated on the efficient manner in which they have discharged it H B MILNER

Short Reviews

A Short Course in Elementary Meteorology By W H Pick (M O 247) Fourth edition completely revised Pp 143 (London H M Stationery Office 1933) 2*s* 6*d* net

THE material of this book is divided into three parts under the headings general meteorology synoptic meteorology and the upper air the first part dealing with wind temperature humidity and ordinary weather phenomena the second with the modern synoptic weather chart and the systems of forecasting based upon it and the third with the physical structure of the atmosphere from the ground up to the highest levels to which recording instruments have been taken by sounding balloons

The descriptions are generally clear and contain few of the inaccuracies which are so common in most works of this scope The author rightly emphasises in the introductory chapter how important it is for the student to remember always that meteorology is a branch of the wider science of physics It is however from the point of view of physics that objection may be made to some of the author s statements for example when he discusses (pp 16–17) the diurnal range of temperature on land and on sea he attributes part of the greater magnitude of the former to the action of the principle that a good radiator is also a good absorber but overlooks the fact that it is largely the absorption of radiation of short wave length (visible radiation) that has to be considered during the daytime and that even if it be demonstrable that the solid surface of the earth absorbs such radiation better than does water it does not follow that the land is a better radiator for the much longer wave lengths emitted at night A small error deserves notice in section 102 (p 95) where it is stated that in the northern hemisphere the eye of a tropical cyclone generally moves eastwards As it is the active stage of a cyclone that is being discussed the movement would be nearly always westwards whether in the northern or southern hemisphere for these storms spend a large proportion of their active life within the tropics E V N

Annual Reports on the Progress of Chemistry for 1933 Vol 30 Pp 462 (London The Chemical Society, 1934) 10*s* 6*d*

THE series of reports for 1933 deals with general and physical, inorganic, organic and analytical chemistry, biochemistry, radioactivity and subatomic phenomena, and crystallography, and forms a substantial contribution to the literature of the science As in former years, the plan adopted is to discuss progress in a limited number of special subjects rather than to attempt a comprehensive survey, a task which would indeed be impossible within the accepted limits of space and cost Thus, for example, Mr R P Bell discusses solubility and related phenomena, Mr J H Wolfenden s section on electrochemistry is confined to 'heavy hydrogen', the structure of water, and the mechanism of hydrogen and oxygen electrode processes and in the biochemistry section space is devoted to a review of progress in the biochemistry of bacteria during the past three or four years Analytical chemistry is represented by discussions of the polarographic spectroscopic and magneto optic methods the physical properties of solutions an extended account of electrometric methods and a section on gas analysis Dr A S Russell examines *inter alia*, advances in artificial disintegration and the positive electron, whilst Dr G A R Kon discusses in some detail the considerations which have recently led to the establishment of the main structural outlines of the sterols and bile acids

Among research chemists this series of annual reports is recognised as providing extremely valuable and authoritative surveys, among teachers of chemistry it is regarded as affording the best means of keeping abreast of modern developments Workers in related sciences, although not requiring to make a study of every chapter, will nevertheless find in this book a great deal of valuable information and explanation, some of which may prove of prime significance in their own researches A A E

(1) *Pink Disease (Infantile Acrodynia)* By Dr Ch Rocaz Translated by Dr Ian Jeffreys Wood Pp v+153
(2) *Infantilism* By Dr E Apert Translated by Dr R W B Ellis Pp v+117+4 plates (London Martin Hopkinson, Ltd, 1933) 7*s* 6*d* net each

THE translation into English of these two French monographs provides interesting and valuable additions to medical literature

(1) "Pink Disease' is the title given to Dr I J Wood's translation of "L'Acrodynie Infantile", which is a comprehensive survey of an illness the obscure nature of which is indicated by the numerous names it has received A full historical, clinical and pathological review is given, and the conclusion is reached that the disease is an inflammation of the nervous system closely allied to epidemic encephalitis It is probably extremely rare in Great Britain, but its apparent tendency to occur in small outbreaks makes it important that physicians should have some knowledge of it The long bibliography included provides references for those who wish to make a detailed study of the subject

(2) Infantilism ' describes in detail the many varieties of the well known state of retarded development, and includes a chapter on the less familiar condition of regression after mature development known as Gandy s retrograde infantilism As textbooks of neurology and pediatrics make but scanty reference to these disorders, and offer little or no therapeutic indications, it is significant to find a whole chapter of this book devoted to treatment

Both monographs are particularly well illustrated

The Method and Theory of Ethnology an Essay in Criticism By Paul Radin Pp xv+278 (New York McGraw Hill Book Co, Inc London McGraw Hill Publishing Co, Ltd, 1933) 15*s* net

ETHNOLOGY is defined by Dr Paul Radin as the description of aboriginal culture, and the object of this essay in ethnological criticism is to show how far the various schools of thought fail to attain the object of the study The evolutionary school, of which Tylor is regarded as the founder and the chief exponent as might be expected, is sharply criticised for various reasons, of which the principal is that it regarded the study of primitive peoples as an evolution of culture and also looked upon its material as representing a phase anterior to that of civilised man of to day Hence the theory of survivals Other schools, the diffusionists', the functionalists, and in America the followers of Prof Boas, are alike criticised from the point of view of the author that ethnology is a purely historical science, and that as such it must treat each phase and manifestation of culture as individual

Chemistry and Physics for Botany and Biology Students By Dr E R Spratt Second edition Pp vii+284 (London University Tutorial Press, Ltd, 1933) 3*s* 6*d*

THIS up to date little book is designed, in particular, to include the sections on elementary chemistry and physics in the syllabuses of botany and biology of the Oxford and Cambridge School Certificate examinations, and emphasises the applications of physical and chemical phenomena to plant and animal life The second edition has been revised and extended to deal with magnetism and electricity, light, electrolytic dissociation and hydrogen ion concentration, the structure of the atom and valency

It can be recommended without reserve to students as indicated in its title, and should, in addition, meet the needs of students in general or of classes requiring a sound and inexpensive course in general science N M B

Liquefaction of Helium by an Adiabatic Method without Pre-cooling with Liquid Hydrogen

By Prof P Kapitza, F R S, Royal Society Mond Laboratory, Cambridge

THE methods for the continuous liquefaction of hydrogen and helium at present in use are essentially the same as those originally used by Dewar and Kamerlingh Onnes when these gases were first liquefied These methods are based on the use of the Joule Thomson effect combined with a regenerating heat exchange after the gas has been cooled below its conversion temperature by liquid air or hydrogen Since these processes are essentially non reversible the efficiency of the method is very low for example, Meissner[1] calculates that to produce liquid helium one hundred times more power is required than if the process could be done reversibly The advantages to be gained by using adiabatic expansion for the cooling of liquefying gases have long been realised, but owing to technical difficulties this method has only been used up to the present to liquefy small amounts of gas by a single expansion Thus in 1895, Olszewski was the first to obtain a fog of liquid hydrogen drops by a sudden expansion of compressed hydrogen Recently, Simon[2] has produced appreciable quantities of liquid helium also by a sudden expansion of highly compressed helium

The technical difficulties in constructing an apparatus for continuous liquefaction by adiabatic expansion lie chiefly in the designing of a cooling expansion engine which will work at low temperatures Two principal types of expansion engine can be considered The first is a turbine, but this involves a number of technical difficulties which have not yet been overcome The second type of machine is a reciprocating moving piston expansion engine, this also involves great difficulties chiefly arising from the difficulty of finding a lubricant which will make the piston tight in the cylinder and retain its lubricating properties at the very low temperatures Claude, however, managed to make such an expansion engine which would work at the temperature of liquid air by using the liquefied gas as the lubricant This method, however, does not appear to be practicable for liquefying helium and hydrogen

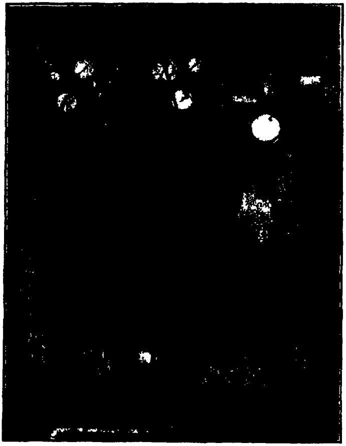

Fig 1 Helium liquefaction apparatus at the Royal Society Mond Laboratory

During the last year, in our laboratory we have been working on the development of a reciprocating expansion engine working on a different principle which does not require any lubrication of the piston at all, and which will work at any temperature The main feature of the method is that the piston is loosely fitted in the cylinder with a definite clearance, and when the gas is introduced into the cylinder at high pressure, it is allowed to escape freely through the gap between the cylinder and the piston The expansion engine is arranged in such a way that the piston moves very rapidly on the expanding stroke, and the expansion takes place in such a small fraction of a second that the amount of gas escaping through the gap is very small and does not appreciably affect the efficiency of the machine

The principal difficulty in constructing such a machine was concerned with the valves in the expansion engine, which had to let in a considerable amount of gas in a small fraction of a second Another difficulty was to find metals with the necessary mechanical properties for use at these low temperatures All these difficulties have now been successfully overcome, and the liquefier is shown in the accompanying photograph (Fig 1)

The expansion engine is placed in the middle of the evacuated cylindrical copper casing, the dimensions of which are 75 cm long and 25 cm diameter The casing also contains heat exchanging spirals and a container of liquid air for the preliminary cooling of the helium Helium is compressed to 25–30 atmospheres and is first cooled to the temperature of liquid air and then cooled by the expansion engine and regenerating spiral to about 8° K , the final liquefaction is produced by making use of the Joule Thomson effect This combination proves to be the most efficient method of liquefaction The liquid helium is drawn off from the bottom of the liquefier by means of a tap

Following the preliminary cooling to the temperature of liquid nitrogen, the liquefier starts after 45 minutes to liquefy helium at a rate of 1 litre per hour consuming about 3 litres of liquid air per litre of liquid helium This output we hope will shortly be increased, but even now it compares very favourably with the original method of making liquid helium in which, according to Meissner (*loc cit*), the consumption is 6 litres of liquid air plus 5 litres of liquid hydrogen per litre of liquid helium It is also evidently a considerable advantage to be able to dispense with liquid hydrogen as a preliminary cooling agent Theoretically it would be possible in our case also to dispense with liquid air but the size of the liquefier would then be impracticably large Using liquid hydrogen as a cooling agent the output of the liquefier could be increased about six times

The same liquefier has also been used for liquefying hydrogen which was passed through a special circuit under a pressure of a few atmospheres

A detailed description of the apparatus will shortly be published elsewhere

Science and the Royal Academy

IF the art of the painter were to begin and end in mere representation, the coloured photograph would completely satisfy most people Indeed, science, by the invention of the stereoscope, has furnished a means of actual representation in three dimensions which far surpasses in this respect even the greatest paintings that exist It is a commonplace to hear, in any gallery expressions of approval or otherwise based mainly upon such considerations

Sir Joshua Reynolds, in his sixth discourse before the Royal Academy, says When the arts were in their infancy, the power of merely drawing the likeness of any object was considered one of its greatest efforts The common people, ignorant of the principles of art, talk the same language even to this day " On the other hand Carlyle, quoting Goethe, points out that 'In every object there is inexhaustible meaning the eye sees in it what the eye brings means of seeing The colour arrangement style or texture, design and rhythm can only fully appeal to those who have given the matter some thought, and who realise that Art is Nature expressed through a personality

Yet there must be rules underlying the making of a picture which give to it those fundamental qualities that ensure its survival through the ages Although science has given the painter a wider range of reliable pigments, and the oils and mediums used by him are more refined and less liable to change, it is interesting to notice that this craft still employs identically the same kind of tools and methods that have been in use for centuries The development of machinery, the vast accumulation of knowledge in all branches of human activity, the great advances in chemistry and physics, leave the artist undisturbed with his simple appliances He still works in surroundings very similar to those that could have been found in the studios of Michael Angelo or Titian The artist is probably unique in this and acquires therefrom a peculiar position in the scheme of things , often being regarded by the ignorant as a kind of magician, by the intelligentsia as a species of poet and sometimes by men of science as an overrated member of society who seems in fact to have contributed nothing to the accumulations of unsorted knowledge

A possible remedy for this state of affairs lies with the artists themselves The old masters have left us pictures of the alchemist in his laboratory Present day artists have missed a great opportunity in not attempting to represent something of the atmosphere in which modern scientific experiments are frequently conducted Surely there is wide scope here for artistic adventure It is not merely a question of depicting some distinguished individual before a background of scientific apparatus The figures some in action and others eagerly note taking, should be subsidiary to the general plan There is often great beauty of colour and composition to be found—especially in a physics laboratory—where some important work is afoot and being carried through, in dim light stabbed only by beams reflected from the instruments

The one hundred and sixty sixth annual exhibition of the Royal Academy, which was opened to the public on May 7, includes the famous bust of Prof Einstein (1593) by Mr Jacob Epstein This has been purchased for the nation under the terms of the Chantrey Bequest There is also a good portrait of Sir Robert Mond (146), painted by Mr F O Salisbury, and an excellent picture of Prof John Walton (with a microscope at his elbow) (248) by Mr W O Hutchison An attempt to portray a situation of scientific interest may be seen in No 167, entitled "The Wilson Observer, 1933", by Winifred M Abram The portrait of Sir Almroth Wright (28) by Mr Gerald F Kelly exhibits a quality which will please all who are satisfied with photographic accuracy Other portraits likely to interest readers of NATURE are those of Major C H Douglas, consulting engineer and economist (3), by Mr Augustus E John, R.A., Prof H M Macdonald, professor of mathematics in the University of Aberdeen (254), by Mr R G Eves, Sir George Buckston Browne (1096), a miniature by Mr P Buckman Since the portraits exhibited at the Academy are often of especial interest, a small additional index to them might with advantage be included in the catalogue

The work of Mr Terrick Williams, R A, entitled 'Sun and Mist, Mousehole" (19), is interesting as representing some beautiful changes in appearances due to the dispersion of light through an atmosphere laden with warm vapour

One outstanding feature of this year's exhibition is the large scale model (1 in to 4 ft) of the Metropolitan Cathedral of Liverpool, made by Mr John B Thorp, to the designs of Sir Edwin Lutyens, R A Finally, we may direct attention to the remarkable metallic sheen upon the herald's coat in the portrait of Sir Gerald Wollaston, Garter Principal King of Arms (237) by Mr Harold Knight The brilliant lustre of polished gold is perfectly imitated, merely by the skilful use of suitable pigments

Dr. Boys on Gas Calorimetry

THE nineteenth Guthrie lecture of the Physical Society was delivered on May 4 by Dr C V Boys, one of the Gas Referees, who took as his subject 'My Recent Progress in Gas Calorimetry" Lord Rayleigh presided

After referring to his very close association with Prof Guthrie Dr Boys remarked that the making of specious scientific surmises unsupported by experiment, however amusing it may be as a pastime or however loudly it may be advertised, does nothing to advance the certain knowledge of the world the acid test of experiment is essential So will you who in years to come will have the management of this Society in your hands, accept this as a solemn message from the dead If you would be true to the ideals of Guthrie, you will seek for a Guthrie lecturer from among those who have done things rather than from those who have merely talked

Proceeding Dr Boys stated that he had not been entirely satisfied with the gas calorimeters he had already invented, but now, as the result of work extending over the last nine years, he had designed a calorimeter which gave him complete satisfaction The essentials of a water flow calorimeter for measuring the heating value of gas comprise a stream of water to be heated by the combustion of a supply of gas, and means for indicating or recording the resulting rise of temperature of the water stream As the volume of a given mass of gas depends on its temperature and pressure, it is clear that means must be provided either to correct such volume to standard conditions of temperature and pressure, or alternatively to ensure that water shall flow through the calorimeter at a rate proportional to the uncorrected density of the gas, that is, inversely proportional to the volume at the time of a standard volume of gas

In his previous recording calorimeter, Dr Boys utilised the first of these alternatives, in the present instrument (Fig 1) the latter alternative is adopted The appropriate hyperbolic relation is realised practically by a device which ensures that the depth of water in the vessel *A* is proportional to the density of the gas, and that water is picked up from this vessel and delivered to the calorimeter *F* in this same proportion The device comprises (1) the closed burette tube, *D*, containing air or other gas, carried on the radial arm, *C*, and immersed at its lower open end in a vessel containing mercury, (2) four rotating scoops carried on arms for collecting distilled water from the lower vessel *B* and delivering it to the upper vessel, *A*, these pick up rather more than is required for the calorimeter water, (3) a pair of rotating scoops and delivery vessels, of which one is shown at *E* for collecting the appropriate volume of water from *A* and delivering same to the calorimeter proper, *F* The excess of water escapes from a siphon carried by the arm *C*, thus maintaining the required level The motive power for driving the mechanism is derived via a Meccano' chain from the small electric motor shown at *H* The water flow system requires the addition of only about 1 gallon of water per annum to replace that lost by evaporation

The gas pump, *G*, for supplying gas to the calorimeter, incorporates a number of novel features Hitherto, the calorific value of gas supplied for towns' use has been measured with reference to a volume of gas saturated with water vapour, at atmospheric temperature Within recent years, there has been an increasing tendency on the part of gas companies to supply dried gas, that is, gas from which a very considerable proportion of the water vapour ordinarily present has been removed In order that the calorific value of such, or any other, gas shall be measured with reference to its actual water vapour content, whether saturated or unsaturated, the gas pump, *G*, uses mercury as confining liquid Briefly, the pump comprises an inner cylinder having six longitudinal compartments accurately reamed out, and rotating within an outer casing Appropriate inlet and outlet ports are provided for each compartment The same small electric motor *H* driving the water supply device rotates the inner drum of the gas pump and causes gas to be delivered to the calorimeter proper *F* at a constant rate of ½ cub ft of gas per hour The volume of gas is accurately determined from the known dimensions of the pump Water levelling which is an essential and troublesome operation with all existing forms of wet meter in order that the gas volume may be accurately known is no longer necessary

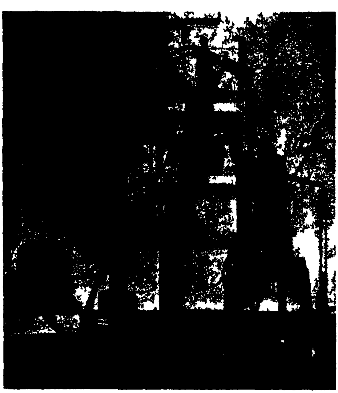

Fig 1 Dr Boys s new gas calorimeter

The calorimeter *F* is of very small thermal capacity so that a reading of outlet water temperature steady to within about 0·01° C is attained in about 15 minutes and this despite the fact that with the calorimeter as at present constructed the flow of water through the calorimeter is intermittent in character Later if found preferable the water flow will be made continuous The gas burns at the end of a small tube made of Pyrex glass which is carried by the arrangement including a Watt parallel motion device shown at *J* The tubes of this parallel motion device can be used for supplying gas and oxygen to the burner if desired The constructional materials used in the calorimeter comprise ordinary glass for the combustion chamber a Pyrex glass burner tube and brass and German silver the latter being protected by a coating of special bakelite varnish which very effectually prevents corrosion of the base metal by the products of combustion The water flowing through the calorimeter suffers no deterioration owing to its passage and is re circulated The rise of temperature of the water is a measure of the calorific value of the gas supply and can be observed by thermometers inserted respectively in the inlet and outlet water or can be recorded by thermometers preferably of the electrical type connected with an electric recorder

Concluding his remarks Dr Boys stated that he had carried out the whole of the work single handed and had constructed the whole of the apparatus himself For sixty years the Gas Referees have been men of high scientific distinction My predecessors were Sir Arthur Rücker and Prof Tyndall and my colleagues and their predecessors were of equal standing This has always been considered necessary because of the technical difficulties of the questions which they had to decide The Gas Referees have been in the position of judges between the gas maker and the gas consumer Though provision for appeal on their decisions is available no appeal in all that time has ever been made and heard Now the Board of Trade is knocking at the door of Parliament to replace the Gas Referees by the cumbersome machinery of the Civil Service

Dr Charles Carpenter president of the South Metropolitan Gas Co expressed his very high appreciation of the work done for the gas industry by the Gas Referees and stated that he was unable to understand how the Government is being so misguided as to recommend the abolition of these posts

Obituary

Prof A B Macallum F R S

PROF A B MACALLUM who died on April 5 at London Ontario in his seventy sixth year may be regarded as the pioneer of general physiology in Canada Educated at the University of Toronto he received his training in physiology under Newell Martin in the then newly organised Johns Hopkins University Returning to his *alma mater* in 1887 as lecturer in physiology on the staff of biology under Ramsay Wright he devoted himself to investigations bearing on the interpretation of microchemical reactions

Macallum s first paper on the demonstration of iron in chromatin was published in 1891 (*Proc Roy Soc* 50 277) and it was followed two years later by a second one (*J Physiol* 26 268 1893) dealing with the path of absorption of this element from the alimentary canal Methods were then tested and elaborated for the micro-chemical demonstration in cells and tissues of other elements, especially phosphorus, potassium, calcium and chlorine He showed (*Proc Roy Soc* , B, 76, 217 , 1905) that the colour reaction which tissues give under the influence of light when impregnated with nitrate of silver is not due, as had been supposed, to protein itself but to halogens, so that this staining method could be used for determining the distribution of chlorides in various cytological elements

Being a keen student of the then rapidly expanding knowledge of physical chemistry, Macallum saw the possibility of using micro-chemical reactions to investigate the position in the cell of adsorbed ions and of thereby determining the extent to which this might be influenced by surface tension Realising that the chloride reaction was independable for this purpose, because of slow penetration of the reagent, he devised a method by which potassium can be identified microchemically through its precipitation with hexanitrite of cobalt and sodium (*J Physiol* , 32, 95 , 1905) He showed that when proper precautions are taken, the reagent penetrates the cell rapidly and that the position of the yellowish compound which it forms with potassium can be revealed by subsequent treatment with ammonium sulphide

A thorough investigation, extending over several years, was then made of the distribution of potassium in plant and animal cells, and it was found that the element is concentrated in regions of the cell in a manner to suggest that alterations in surface tension are responsible In a review of these researches published in 1911 in *Ergebnisse der Physiologie*, there is a full discussion of the hypothesis that the properties of division and movement in cells, as well as of secretion and absorption, can be attributed in part, at least, to surface tension phenomena In a later discussion of his results (1913) (Presidential Address, Soc of Biol Chem), Macallum advanced the view that the chief factor in muscular contraction "is the attraction between the molecules constituting the superficial film of a sarcostyle and forming an interface with the sarcoplasm surrounding the sarcostyle" This attraction, which is the cause of the surface tension, is not equal throughout the doubly refracting discs, as is shown by the fact that potassium salts are localised at the ends of the longitudinal axis, indicating, according to the Gibbs Thomson principle, that the surface tension is lower here than on the lateral surfaces During contraction, the discs tend to become spherical because the surface tension of the lateral surfaces becomes less Speculations follow concerning the relationship of the breakdown of the lactic acid precursor to these changes in surface tension, and the paper is interesting reading in the light of the more recent researches in this field

Macallum also made numerous observations by chemical methods of the percentage amounts of inorganic ions in the tissues and body fluids of various animals He showed that when regard is paid to the relative proportions of sodium, potassium and calcium, rather than to the absolute concentrations of these ions, there is a striking resemblance between the composition of the ocean and the inorganic composition of the blood plasma of mammals His first paper in this field appeared in 1903 (on "The Inorganic Composition of the Medusæ", *J Physiol* , 29) and the conclusions there drawn are sustained in a second one published in 1910 ("The Inorganic Composition of the Blood of Vertebrates and Invertebrates and its Origin", *Proc Roy Soc*) in which there is a discussion of the relationship of the development of the kidneys to the inorganic composition of the blood plasma of various marine invertebrates and vertebrates In this paper Macallum points out that the establishment of a constant internal medium was the first step in the evolution of vertebrates from an invertebrate form and advances the view that the kidney was essentially the first typically vertebrate organ

Throughout all his investigations, Macallum maintained a broad philosophical outlook and his thorough knowledge of biology and indeed of natural science in general enabled him to find various applications for the results of his laboratory investigations As examples may be mentioned papers dealing with the origin of life on the globe (read before the Royal Canadian Institute about the year 1903) and the physical and chemical factors in heredity (address as president of the Biological Section of the Royal Society of Canada in 1910)

No account of Macallum's career would be complete that did not refer to his painstaking work from 1916 until 1921 as the first administrative chairman of the Advisory Council for Scientific and Industrial Research of Canada His influence on the development of scientific research in the Dominion has been very great, partly through his active participation in the work of the Royal Canadian Institute and the Royal Society of Canada, and partly through his association first with the University of Toronto and latterly with that of McGill in Montreal

Macallum was a man of imposing presence and forceful character, and it will be long before he is forgotten in Canadian scientific circles

J J R M

DR E W WASHBURN

DR EDWARD WIGHT WASHBURN, who died on February 6 at the age of fifty-two years, was the chief of the Division of Chemistry of the U S Bureau of Standards at Washington He was well-known to a wide circle as a physical chemist of distinction and the author of an "Introduction to the Principles of Physical Chemistry"

Washburn was a graduate of the Massachusetts Institute of Technology, where he was a pioneer in the study of the hydration of the ions in aqueous electrolytes From 1908 until 1922 he held appointments in physical chemistry and then in ceramic engineering at the University of Illinois, where he produced a long series of scientific and technical papers Then, during a period of four years, he undertook the Herculean task of editing the 'International Critical Tables", a task which was rendered supremely difficult by the fact that it had to be undertaken *de novo* instead of undergoing a progressive development The completed tables, which have recently been made much more accessible and easy to use by the addition of a new index volume, will remain as a monument to Washburn's patience and skill, and are likely for many years to serve as a foundation, to which successive volumes of the "Annual Tables may be added in order to maintain the up to date character of the whole edifice

When appointed to the Bureau of Standards in 1926, Washburn undertook a wide programme of investigation and research, from which two items may be selected for comment The first was the remarkable achievement of preparing crystals of rubber, by distillation under extreme conditions of low pressure and short distance, in which Washburn was keenly interested when I visited him at the Bureau of Standards in 1930 The second, which will perhaps be appreciated more widely than any other feature of his career was his discovery in January 1931 of the fractionation of light and heavy water by the process of electrolysis The separation of isotopes on a practical scale marks the beginning of a new period in chemistry, and, since Washburn's method of separation is already being developed as a manufacturing process, his name will long be remembered as the originator of this new period

T M LOWRY

DR L R FARNELL

WE regret to record the death of Dr L R Farnell, formerly rector of Exeter College, Oxford, and the well known authority on the religious cults of ancient Greece, which took place at Parkstone, Dorset, on March 28

Lewis Richard Farnell attained the age of seventy-eight years on January 19 last, having been born at Salisbury in 1856 The second son of John Wilson Farnell, he was educated at the City of London School, of which Dr Evelyn Abbott was then headmaster, and at Exeter College, Oxford, where he won an open classical scholarship Practically the whole of the rest of his life was devoted to the service of his College and University Two years after taking his degree in 1878, with first-class honours in both Classical Moderations and *Literæ Humaniores*, he was elected to a fellowship of his College He then studied classical archæology in Germany and travelled in Greece and Asia Minor, returning to Oxford to serve Exeter as tutor, sub rector, senior tutor and dean, and from 1914 until 1928 as rector, in which office he succeeded the late Dr W W Jackson

His studies in classical archæology, more especially of the attributes of the gods as represented in art, led Farnell to the comparative study of Greek religious cults He rapidly attained a high reputation as an interpreter of obscure passages in Greek literature in the light of his research His greatest achievement, however, was his monumental work "The Cults of the Greek States" in five volumes, which appeared between 1896 and 1909, with a supplemental volume on hero cults, published in 1921 In this work Farnell showed a mastery of detail which was equal to, if it did not surpass that of the best German scholarship of the day combined with an unusually wide knowledge of comparative material His contribution to the study of Greek culture is original in conception, fundamental and epoch making

Farnell was also the author of a number of smaller works, dealing with the religions of Greece and the ancient East and with comparative religion, in which he showed a great gift of lucid, semi popular exposition, combined with sound scholarship He was a frequent and valued contributor to the learned periodicals concerned with his special studies

In 1901 Farnell was one of the first to receive the newly instituted degree of D Litt of his University He was University lecturer in classical archæology from 1905 until 1914, the first Wilde lecturer in natural and comparative religion, Hibbert lecturer in 1911, and Gifford lecturer in 1919 He served as Vice Chancellor of the University in 1920–1923 If he required a high standard from his pupils in conduct, industry and scholarship, his whole life and work afforded them an admirable example

---

DR ALBIN STOCKÝ, professor of archæology at Prague died on April 18 at the age of fifty eight years He was the author of numerous publications dealing with Bohemia in the Stone and Bronze Ages He had served on various archæological commissions and had given valuable assistance to museums in connexion with the identification of objects dating from prehistoric times

---

WE regret to announce the following deaths

Mr Henry S Hall, formerly head of the military and engineering side at Clifton College, author of many well known textbooks of mathematics, on May 3, aged eighty-five years

Mr Carl Olaf Lundholm, technical adviser to the Nobel Trust in 1909–14, a pioneer in the manufacture of explosives, on May 8, aged eighty-four years

Dr J P van der Stok, director of the Section of Oceanography and Maritime Meteorology at the de Bilt Meteorological Institute, near Utrecht, in 1899–1923, formerly director of the Magnetic and Meteorological Observatory, Batavia, on March 29, aged eighty-three years

News and Views

Royal Society Elections

AT the meeting of the Royal Society held on May 3, the candidates whose names were given in NATURE of March 10, p. 352, as having been selected by the Council for fellowship of the Society, were duly elected. In addition, two foreign members were elected, namely, Prof. H. L. Lebesgue, of Paris, the discoverer of 'Lebesgue integration', and Prof. O. Warburg, of the Kaiser Wilhelm Institut für Zellphysiologie, Berlin-Dahlem, who is known for his work on cellular metabolism and respiration.

Prof. Henri-Léon Lebesgue, For. Mem. R.S.

HENRI LÉON LEBESGUE was born in 1875 at Beauvais, and after studying at the École Normale Supérieure, taught from 1899 until 1902 in the Lycée at Nancy, where he wrote his famous thèse de Doctorat 'Intégrale longueur, aire', which was published in the *Annali di Matematica*, in 1902. After holding academic posts at Rennes and Poitiers, he was appointed in 1910 lecturer at the Faculty of Sciences of Paris, in 1921 professor of mathematics at the Collège de France, and in 1922 a member of the Academy of Sciences. Prof. Lebesgue's reputation was first made by his definitions of the functional operations of integration and derivation, which are of such generality that they may be applied to classes of functions vastly more extensive than the restricted classes to which earlier definitions had been applicable. It was Cauchy who first replaced the geometrical idea of an integral, as an area, by a precise arithmetical definition, regarding it as the limit of a sum of elements $f(x) \Delta x$ when Δx tends to zero; and on this basis he proved theorems of existence and uniqueness. Riemann generalised Cauchy's conception by extending it to certain functions which were discontinuous at points forming sets dense everywhere; but the functions integrable in Riemann's sense are still a limited class.

IN order to obtain a more general definition, Lebesgue first devised a theory of the 'measure' of a set of points, which was a great improvement on the theory of 'content' previously given by Cantor, namely, that the content of the sum of two sets is not in general the sum of their contents, whereas the measure of the sum of two mutually exclusive sets is always the sum of their measures. He then departed from the procedure of Cauchy and Riemann for defining $\int f(x)dx$, by dividing the range of variation of $f(x)$ into intervals (as contrasted with dividing the range of variation of x into intervals), and considering the measures of the sets of points belonging to these intervals, whence a definition of the integral naturally follows. Lebesgue's definitions of integration and derivation have led to developments of far-reaching importance in the theories of Fourier series and other trigonometric series, of singular integrals, integral equations, Dirichlet's problem, the calculus of variations, functional operations, and the properties of analytic functions in the neighbourhood of their singularities.

Prof. O. Warburg, For. Mem. R.S.

PROF. OTTO WARBURG is well known for his very important work on metabolism and respiration in cells. In this work he made extensive use of the manometric technique, which he greatly developed. This method was applied by him and the members of his school to a great variety of biological problems with conspicuous success. By using very thin slices of animal tissues suspended in serum, precise measurements of respiration and other metabolic processes could be made under approximately physiological conditions. By this means he discovered an important difference between the metabolism of normal tissues and that of rapidly proliferating tissues such as tumours, namely, the fact that the latter show a high aerobic glycolysis. By the study of the inhibitory effect of certain specific poisons, such as cyanides and carbon monoxide, on respiration, he showed the important rôle played by catalytic compounds of iron. On studying the effect of light of different wave-lengths on cells poisoned by carbon monoxide, a photochemical absorption spectrum was obtained which was found to be very similar to that of a hæmatin compound. In this way he showed the importance of hæmatin compounds in cell respiration. In the analysis of these effects he displayed remarkable technical genius. In addition to this hæmatin system (known as the respiratory enzyme), Prof. Warburg has recently discovered another important intracellular system involving a different type of catalytic pigment, belonging to the class now known as flavines. Prof. Warburg is also well known for his fine work on photosynthesis.

Bicentenary of Stahl (1660–1734)

Two hundred years ago, on May 14, 1734, Georg Ernst Stahl, the celebrated German physician and chemist, died at Berlin at seventy-three years of age. For many years he had been physician to Frederick I, King of Prussia, and he was widely known for his original views and for his numerous writings. He wrote, edited or superintended no fewer than 250 works. Born at Anspach, Bavaria, on October 21, 1660, at a time when Germany was just recovering from the terrible effects of the Thirty Years War, he studied medicine at Jena; at the age of twenty-seven years became physician to the Duke of Weimar and six years later was appointed professor of medicine, anatomy and chemistry in the newly founded University of Halle. He taught there for twenty-two years (1693–1716), and it was during that time he enunciated the doctrines of vitalism and animism and the theory of phlogiston, the latter a generalisation which did much to make chemistry a science. "The doctrine of phlogiston," says Thorpe, "was embraced by nearly all Stahl's German contemporaries, notably by Marggraf, Neumann, Eller and Pott. It spread into Sweden, and was accepted by Bergmann and Scheele; into France, where it was taught by Duhamel, Rouelle and Macquer; and into Great Britain, where its most influential supporters were Priestley and Cavendish It continued to be the orthodox faith until the last quarter of the eighteenth century, when, after the discovery of oxygen, it was overturned by Lavoisier "

Refrigeration and its Applications

FOR the first of the series of Research and Development Lectures arranged under the auspices of the British Science Guild and delivered at the Royal Institution, Sir William Bragg, on May 2 took as his subject 'Refrigeration" This he pointed out is of great importance to Great Britain, which imports an immense amount of meat, fish, butter and fruit, many hundreds of shiploads of which are received every year The principles underlying refrigeration are comparatively simple, but their application on a commercial scale has involved much research such as is being carried out at Cambridge, the National Physical Laboratory, East Malling and elsewhere Historically, the subject of heat and cold goes back to the early days of the Royal Society, and Hooke's views on fluidity are of much interest In the eighteenth century, the theory of caloric held sway, but it was through the work of Rumford, Davy, Mayer and Joule that it was shown that heat is, in the phrase of Tyndall, a mode of motion, and to day it can be shown that the molecules of substances are all in motion, the rapidity of which is increased by heat and decreased with cold All the phenomena of expansion, compression and evaporation, which are utilised in refrigerating machines, are explained by this theory Throughout the lecture, each step was illustrated by experiments in which billiard balls, bicycle pumps and liquid air played as important a part as thermo couples and galvanometers A singularly beautiful demonstration of the formation of vapour and clouds was given by pouring liquid air on to the surface of warm water lying in a large shallow pan Liquid air was used also to show the alteration in the properties of substances when really cold, rubber becoming brittle and a bell of lead giving a metallic note when cooled in it Sir William referred to the refrigeration exhibition now being held at the Science Museum, and on behalf of the director of the Museum invited all those in the audience to visit it

Electrical Phenomena at Very Low Temperatures

PROF J C McLENNAN gave the twenty fifth Kelvin Lecture before the Institution of Electrical Engineers on April 26, taking as his subject 'Electrical Phenomena at Very Low Temperatures" In 1823 Faraday succeeded in liquefying chlorine and afterwards succeeded in liquefying many other gases, but he failed to liquefy oxygen, nitrogen and hydrogen as he was unable to obtain the requisite low temperature At the end of the War, a large stock of helium was available in Toronto, and this gas was successfully liquefied in 1923, a century after Faraday's experiment with chlorine By evaporating liquid helium and thus reaching an absolute temperature of 0 7° K , Keesom of Leyden successfully solidified this element in February 1932. The liquid was subjected to a pressure of 175 atmospheres and surrounded by rapidly evaporating liquid helium The reason why liquid oxygen, hydrogen and helium are very good insulators is probably because the electrons are closely bound to the nuclei In 1911, Kamerlingh Onnes found that the resistance of mercury vanishes suddenly at 4 2° K and that some other metals behave similarly at definite low temperatures Most metals show no trace of this supraconductivity even when great pains are taken to ensure their purity Certain alloys have been found to become supraconductive This supraconductivity can be destroyed by placing them in a magnetic field The lower the temperature the greater the magnetising force necessary to destroy the supraconductivity By suddenly destroying the magnetic field surrounding a ring of supraconductive metal, a current can be set up in it if its temperature be below the transition point This current is quite independent of the nature of the metal and depends only on the intensity of the original induction It looks as if the results of low temperature research would throw light on the nature of magnetism

The Restrictive Law of Population

IN his Huxley Memorial Lecture under this title, delivered on May 4, Prof Johan Hjort, of the University of Oslo, dealt with a subject which exercised a decisive influence upon the thought of Huxley the question of over population (London Macmillan and Co , Ltd 1s net) Prof Hjort assumes that human society can be studied as a historical group of diverse individuals living in a restricted complex environment, and shows that biology has disclosed the many and various factors which influence the vital processes of the individuals comprising a population and determine the quantity and quality of the population as a whole He defines an optimum population as the minimum number of individuals who can utilise to the full the vital possibilities made available by one or other of those factors Incidentally, he surveys the fishing and whaling industries as examples, and illustrates his point that the conditions in both depend upon the power of regeneration shown by the stock In the case of the whale, technical developments have produced a grave disharmony between the reproductive rate and the death rate, and the problem before the industry is that of defining the optimum catch Restriction of the numbers killed is urgently demanded, but this requires both State intervention and international agreement

ACCORDING to Prof Hjort, the ideal of all social endeavour is the maintenance of the population in a state of permanent equilibrium under conditions of life which are optimal For the achievement of this ideal, society must undertake vast and prolonged biological experimentation Through biology there has come an emancipation from mental chaos and from the belief that human life is governed by irrational chance Biology has shown that over-population, which inevitably arises in certain given natural conditions, is not due to a superficial turmoil of moods and sentiment, but to the operation of natural laws. To-day society has both the knowledge and the power to solve, in its own ways, the problem of population. If there be the possibility of enlargement of the means of subsistence, of renewed expansion, then this should be completely explored; but, if such expansion is impossible, then the aim of society must be to ascertain the limits in which an optimum population can enjoy the maximum of liberty. In both tasks the method must be that of the social experiment. Though Prof. Hjort mainly restricts himself to a discussion of the method of research and experiment in its application to social problems, he does not avoid the conclusion that an economically re-united Europe would afford conditions for a new emancipation, for a recovery of the freedom that the War destroyed. For, he holds, this would bring peace, and peace amongst men is not a natural state of things; it does not make itself but must be made.

Representation of Science on Government Commissions

As announced last week in this column, the Postmaster General is about to set up a committee to consider the development of television and to advise on the conditions under which any public television service should be provided. It is understood that the personnel of the committee is to consist of representatives of the Post Office, the British Broadcasting Corporation and the Department of Scientific and Industrial Research. A committee so constituted, presuming that some of the members have practical knowledge of the problems involved in television, would command that measure of public confidence which is necessary if its deliberations are to find general acceptance; and it would be an advance on many Commissions and committees appointed by the Government in this respect. For reasons which it is difficult to understand, there has been a lamentable tendency on the part of Ministers to pass over scientific men in setting up Royal Commissions, committees, and departmental committees even when matters in which scientific and technical issues are involved.

It is to be hoped that the constitution of the television committee is a sign that the Governmental mind is being quickened in this respect. Time and again we have urged that no body set up to consider any subject with scientific or technical ramifications can be adequate or complete unless it includes scientific workers or technicians in its personnel. The Parliamentary Science Committee—a body representing the British Science Guild, the Association of Scientific Workers, and a number of learned societies—has also taken up the matter, urging the Prime Minister to insist on his colleagues observing this principle. Some fifteen months ago the Postmaster General appointed a Post Office Advisory Committee. If this body is to be of real service it will, presumably, have to advise on technical matters such as telephony and telegraphy. Yet no one with scientific or technical qualifications was appointed amongst a numerous membership. There is now a vacancy occasioned by the death of the Hon. Mary Pickford, thus affording an opportunity of rectifying this state of affairs.

Scientific Method and Politics

The first instalment of a tabular analysis of various social and economic systems, in the form of answers to a questionnaire prepared by the Engineers' Study Group on Economics (Nature, 132, 635, Oct. 21, 1933) is to appear in the forthcoming issue of *Progress*, the organ of the Association of Scientific Workers. The Study Group, apart from research investigations, arranges for discussions on questions of the moment, at which those engaged in any branch of scientific work are welcomed. On May 16 Mr. Harold Macmillan, M.P., will address the Group on "Reconstruction". The meeting will be at 7.45 for 8 p.m. at Denison Hall, 296 Vauxhall Bridge Road, Victoria, and Sir Richard Gregory will take the chair. Tickets may be obtained from the honorary secretary of the Group, Col. P. Johnson, Gunnersbury House, Hounslow, Middlesex.

The interest which scientific workers are beginning to show in social and economic questions is not restricted to Great Britain. In France there are several active groups. The Centre Polytechnicien d'Etudes Economiques (12 rue de Poitiers, Paris; president, M. Gerard Bardet) consists mainly of former students of the Ecole Polytechnique, one of the best known engineering colleges in France, and is now in its third year of existence. Another, the Centre d'Études Économiques de l'Alimentation (39 boulevard de Sebastopol, Paris; president, M. André Roussel) was formed by the fusion of three pre-existing groups drawn from the Ecole Polytechnique, Ecole des Centraux and the Institut Agronomique. Both organisations publish bulletins regularly, giving the results of their studies on economics and production and distribution of foodstuffs.

Unemployment and Poverty in India

In a recent article in the *Karachi Daily Gazette*, Capt. Petavel, formerly lecturer on the poverty problem at the University of Calcutta, strongly advocates the formation of co-operative colonies as a solution of the problems of unemployment and poverty in India. He suggests that the colonies should be open not only to those who have merely their labour to offer, but also to those who would contribute capital, land or equipment. All would be co-operators in their way, and would have a share of the products. The workers' remuneration would be mainly in kind, but part might be in money. This would enable the more ambitious to save, and in time to launch out on any small undertaking they might fancy. If they failed, they could return to the colony, which would thus provide opportunity with security. As the colonies developed, they could adopt a system of exchange tickets redeemable in the produce of the colony. Thus it is claimed purchasing power would always be commensurate with productive power. People could always get work in the colony, because they would get a ticket to take away what they had produced. To reinforce his argument, the author refers to the Swiss Labour Colony at Witzwil and that at Llano in Louisiana

In the former, even people classed as 'unemployables' have been made self supporting In India he suggests a start could most easily be made with an educational co-operative colony in which young persons could work and receive their education Elderly persons might also be included to act as leaders, or to work in departments of their own In order to start a fund for experiment on the lines advocated by Capt Petavel, the Mayor of Karachi has announced that he will give Rs 5,000 and 50 acres of good land near Karachi

Re-equipment of Collieries and Steelworks

IN the supplement to the *Daily Telegraph* of March 19, Dr A H Railing says that the need for the reorganisation of certain of the basic industries of Great Britain is urgent As a result of recent applications of scientific knowledge, great advances have been made in developing new plant for the economic mining of coal and the manufacture of iron and steel products In recent years the grouping of collieries makes it possible to use large turbo machines and thus considerably lowers the cost of generating electric power This solution of the problem of the handling and transport of coal will contribute greatly to the economic success of the undertaking A colliery equipped with a modern coal cleaning installation can command higher prices for its output Loss and waste due to the breakage of coal can now be reduced to a minimum by using anti breakage devices By grouping together iron and steel works it would be possible to utilise the by product gases of the iron and steel industry An installation of large turbo generator units in such a station would enable it to have a thermal efficiency as high as that obtained in the largest modern power station The by product gases from the industry would in this way acquire the same heat value as the coal used in coal fired power stations Many of the rolling mills in Great Britain have been installed for very long periods and their retention in service militates against securing the high quality of product demanded to day An electrically driven rolling mill of modern design can be regarded in the light of a precision tool, capable of an output of material possessing the highest degree of accuracy obtainable in rolling practice The electric furnace also opens out great possibilities One of the valuable properties of the high frequency electric furnace is that, when operating, it gives rise to an automatic stirring action which secures a uniform product

Street Traffic Signals, 1868 1934

IN 1868 the City of Westminster introduced a method of mechanical signalling to help the police to control the traffic A semaphore, having a red and green gas lamp for night use, was employed, but unfortunately an explosion put an abrupt end to this experiment Early in this century, road signals similar to railway signals were used for controlling a few tramways and also the traffic on Tower Bridge So far back as 1918, colour light signals were used to control street traffic in New York The Siemens and General Electric Railway Signal Co (S G E) installed the first modern British traffic signal at a busy road junction in Wolverhampton in 1926 The most recent development of the vehicle actuated signals is the Autoflex' system of the S G E , a full description of which is given in the Engineering Supplement of the *Siemens Magazine* for April It was first brought into use in November 1933 and there are now several installations giving very satisfactory service In this system vehicles approaching a road junction pass over pneumatic detector mats installed in the paths of the various traffic streams and so notify their movements to an electrically operated controller The mats are equivalent to the eyes and ears of a traffic policeman If vehicles leave the intersection on the wrong side of the road the mats are insensitive The top of the mat is rounded and projects slightly above the road level presenting a good striking face, so that it is not possible for high speed vehicles or caterpillar tractors to ride over it without registering If no suitable gap occurs within a predetermined time, the continuous stream is arbitrarily interrupted and the right of way transferred There is no necessity for long amber periods since signal changes take place only when the intersection is clear , two or three seconds are generally sufficient The power required for a controller is only about 30 watts, which is less than that required by an ordinary lamp

Crystalline Structure and Failure of Metals

THE eighth Edgar Marburg lecture of the American Society for Testing Materials was delivered by Dr H J Gough, his subject being Crystalline Structure in Relation to Failure of Metals—especially by Fatigue" Dr Gough dealt almost exclusively with the results of X ray examination of metals and the paper contains what is probably the fullest résumé yet given of the subject Some indication of the ground traversed will be obtained from the fact that the bibliography contains no less than 175 separate references Starting off with a general discussion of the nature of the atomic bond and of the structure of solids in connexion with the basic problem of failure under stress, the methods of preparation of single crystals of metals and crystal structure as revealed by X ray investigation, Dr Gough then proceeded to consider more specifically the distortion of single metallic crystals under simple static stresses, the influence of the crystal boundary upon strength and distortion and the effects of cold working upon single crystals and multicrystalline aggregates Coming to the subject of failure under fatigue' conditions, Dr Gough dealt with metals crystallising in the face centred cubic, in the close-packed hexagonal (discussing incidentally the twinning of zinc), in the body centred cubic, and in the face centred rhombohedral lattices Finally, he considered the behaviour of single crystals as compared with that of multicrystalline metals Dr Gough's conclusions are not yet everywhere accepted, but whatever the individual opinions of readers of the lecture may be, it will be universally welcomed as providing in a readily accessible form, an almost ideal summary of work dispersed throughout a multitude of different publications.

Aerial Surveys for Town Planning

THE urgent necessity for modern town plans required under the Town Planning Act has raised the possibility of meeting the demand by aerial survey In most cases, less than two years remain for the completion of these plans The Ordnance Survey at its existing strength cannot hope to meet this demand A scheme outlined in the *Times* of May 5, however, promises to meet the situation, and the Ordnance Survey has promised its co operation if local authorities make immediate revisions by air survey The scheme would admit of the 16,000,000 acres of town planning areas in England and Wales being covered within two years The country would be divided into sixteen units, of which eight would be photographed concurrently On the reasonable assumption that 30 days in the year would be suitable for vertical photography the work could be done in the two years available Local authorities would be supplied with prints on a scale of 1 : 5000 and a set of transparencies on the same scale as the Ordnance sheets The originators of the method are Messrs H Hemming, Ltd , and Economic Air Surveys, Ltd The fully revised Ordnance sheets would follow later

Aerial Surveys in the United States

AN extended scheme of aerial mapping in the southern States is planned under the United States Geological Survey in co-operation with the Shore and Geodetic Survey, the Census Bureau and other Federal bodies The area to be covered, according to a report issued by Science Service, of Washington D C is 40,000 square miles, selected from agencies in the States of Alabama, Arizona, Arkansas, California, Georgia, Louisiana, Mississippi, New Mexico, South Carolina, Texas and the District of Columbia The maps will be used primarily in connexion with the agricultural census to be made in November next, but will have a permanent use as State records and for other purposes The need for a more systematic land survey is indicated by the fact that air reconnaissances have already revealed the existence of vacant farms and waste lands not under cultivation hitherto unrecorded and consequently in some instances escaping taxation There may be an extension of the scheme later to cover 1,000,000 square miles As at present planned, it will take seventy days to complete at a cost of 650,000 dollars The aeroplanes will have the co operation of link men on the ground under observation, and altogether 500 engineers with 1,500 assistants will be employed The scheme is part of the programme of the Civil Works Administration for the relief of unemployment

Records of the Maya

STUDENTS of American archæology will welcome the publication by the Carnegie Institution of Washington of "The Book of Chilam Balam of Chumayel"—the Book of Balam the Prophet, which, giving an account of certain matters pertaining to ritual and belief as recorded by the ancient Maya in their own language, is one of the most important pieces of documentary evidence relating to the early history of Yucatan known to scholars The book has been edited by Mr Ralph L Roys, who for the first time has applied the principles of classical scholarship to the establishment of a standard text The text is accompanied by a translation and annotations by the editor There are several versions of the Book of the Prophet Balam, each known by the name of the village to which it belonged originally, such as that of Tizimin, Ixil, or Nah That of Chumayel, with those of Tizimin and Mani, have the greatest value for the study of Maya civilisation Chilam Balam, whose prophecies are recorded among the matter in his book, lived at the end of the fifteenth century and the beginning of the sixteenth The Chumayel version dates only from 1782, but there is little doubt that the greater part of it has a pedigree as an authentic copy going back to the sixteenth century when the Maya wrote down in the European script, but in their own language, prophecies, chronicles, rituals, myths, calendrical matter and medical treatises, much of which would appear to have been transcribed directly from the hieroglyphic manuscripts afterwards destroyed and proscribed by the Spaniards The original manuscript of the Chumayel version has disappeared, and the present text has been prepared from photographic copies

Nature Sanctuaries in Zululand

NATAL possesses five sanctuaries for wild life, and all, with the exception of the bird sanctuary at St Lucia and False Bay, have special interest on account of the rare mammals they contain—the Umfolosi has the only surviving herd of the southern white rhinoceros The reserves have been threatened to some degree because of the fear that their mammals preserved a reservoir of the trypanosomes of the cattle disease, nagana But it may be accepted that the destruction of big game is a futile method of controlling the tsetse borne disease, and that the reserves may well be retained, since they occupy areas unfitted for agriculture on account of endemic nagana, malaria, insufficient rainfall or poverty of soil Indeed, in a pamphlet on Natal's Nature Sanctuaries in Zululand" E K du Plessis urges that they should be properly established and made statutory, that they should be provided with suitable approaches to encourage tourist traffic, and that they should be surrounded by a three-mile buffer zone, to prevent shooting parties from slaying animals on the very border of the reserve It is further suggested that the shooting season should close at the end of September, since the does are in young by October, and that all year licences for shooting should be discontinued

Lancashire and Cheshire Fauna Records

THE issue of the nineteenth annual report of the Lancashire and Cheshire Fauna Committee for the year 1932 adds *Plastosciara Egertoni*, from Rostherne Mere, Cheshire, as a new species to science, while a list of a hundred new species added to the faunistic records for the two counties includes 38 Mallophaga on the birds and mammals, which Mr H Britten is investigating, 20 Diptera, 17 sawflies, 10 Coleoptera, 9 Hymenoptera, 3 Anoplura, and one each of Lepidoptera, Arachnida and mites The avi fauna records for the year include the nesting of the golden eye and of the pochard in Cheshire for the first time, and the occurrence of a flock of knots (*Calidris canutus*), estimated to number 7,000, on the Lancashire coast in July White fronted geese and grey lag geese are increasing in north Lancashire in winter, while tufted ducks, teal, shoveller and little owl are also reported to be increasing in parts The main colony of Sandwich terns on Walney Island Lancashire was wiped out by the herring and lesser black backed gulls the colony of which, established five years ago, has assumed alarming proportions The terns from Walney went to nest at Ravenglass ternery where the Sandwich terns have increased from 12 pairs in 1930 to 70 in 1931, and 370 in 1932 The ruff (*Philomachus pugnax*) is still a regular autumn migrant and records are made of the wood sandpiper (*Tringa glareola*), green sandpiper (*T ochropus*), greenshank (*T nebularia*) and grey phalarope (*Phalaropus fulicarius*) on passage, while large numbers of black tailed godwits were seen in the spring on the coast The Fauna Committee announces that it will dedicate Part 2 of its Check List of the Fauna of Lancashire and Cheshire' to the late T A Coward, for many years one of the recorders of the Committee, Part 1 having been issued in 1930 Mr A W Boyd is president of the Committee and H E Britten, Prof S J Hickson and W Mansbridge vice presidents

National Museum of Wales

THE annual report for 1932–33 of the National Museum of Wales shows with what fine spirit the people of Wales are supporting their progressive Museum The opening of the exhibition galleries in the east wing threatened to be marred by the existence of a considerable debt upon the building, but a public appeal has resulted in the receipt of more than three hundred contributions, so that, as promised moneys come in, the debt will be finally extinguished The Folk Industries Gallery in the new wing was opened to the public in July 1933 It illustrates a side of museum activity of much interest to the public Amongst the exhibits are the plant of a woollen yarn factory, and series showing the whole range of the woollen industry in Wales, cider making, sawing, fishing and pottery making An early cast iron gate, an engine from Neath Abbey Iron Works and an early colliery tram illustrate the transition effected by the Industrial Revolution Special reference should be made to the reconstructions of a rural smithy and a wood turner's shop

Cabbages and Related Crops

THE second edition of Bulletin No. 53 of the Ministry of Agriculture ("Cabbages and Related Green Crops", H M Stationery Office, pp 60 1*s* 3*d* net) was issued in November 1933 It deals with the commercially useful variants of the wild *Brassica oleracea*, namely, cabbages and savoys, Brussels sprouts, cauliflowers, broccoli and kale Details of cultivation in many districts are combined with extensive notes on the economic uses of various products, and numerous methods of marketing are given Production and harvesting of seed are also discussed The volume is designed to help the grower, and should do this effectively A chapter on the cultivation of *Brassica* as farm crops has been added to the material published in the first edition, and the whole text has been improved by the incorporation of much recent knowledge

Liverpool Observatory

THE report of the Liverpool Observatory and Tidal Institute for 1933 records several interesting matters concerning tidal records Experiments were made with seismographs with the view of recording the tilting of the earth due to tidal loads as well as to thermal effects An instability in the records was traced to distortion in the structure supporting the instruments This was overcome and satisfactory records were obtained The work is being continued with improvements in the instruments Another important piece of work concerns a new method of prediction of mixed diurnal and semi diurnal tides Work was also done on the tidal bore of the Trent and on the tides of the Bay of Biscay Tidal predictions have been worked out for various authorities

Rainfall of the World

MOST maps hitherto constructed to show the mean annual distribution of rainfall are confined to the land areas and have no indication of rainfall over the oceans Prof W Meinardus has published in *Petermanns Mitteilungen* (1934) a new rainfall map on a scale of 1 100 000,000 which shows the distribution over the entire surface of the globe On so small a scale it naturally does not differ materially so far as land areas are concerned from Supan's and other maps, although it shows effectively the low precipitation in north and south polar regions, but over the oceans, and in particular the Indian and Pacific Oceans, there is much of interest These details have been taken chiefly from G Schott's oceanic maps The map is produced in tints of two colours showing six different grades of rainfall.

Study of Cosmic Rays in Armenia

PROF A F JOFFE, of the Physico Technical Institute of the U S S R, is sending out a scientific expedition to Erivan to establish a laboratory for the study of the cosmic rays It is proposed to set up the station on Mount Alagöz, in Armenia, at a height of 14,400 ft above sea level The object of this station will be to investigate the distribution of the cosmic rays The leader of the expedition is Dr D V Skobeltzin It has also been decided to set up on the shore of Lake Gokcha (6,345 ft above sea level) an astrophysical observatory where a 16 in reflector will be erected

Announcements

Sir Sidney Harmer, formerly director of the Natural History Departments, British Museum, has been awarded the Gold Medal of the Linnean Society The medal will be presented at the annual general meeting on May 24

Prof Victor Van Straelen, director of the Royal Belgian Natural History Museum and formerly vice president of the Parc National Albert in the Belgian Congo, has been appointed president of the Parc National Albert in succession to King Leopold III, who held the office of president until the death of his father, King Albert

We are glad to learn that the Belgian Parliament has now made ample provision for the preservation of the unique collection of skeletons of the Wealden Dinosaur Iguanodon in the Royal Museum of Natural History Brussels, to which we referred on March 3 (p 320) The late King Albert, who was always deeply interested in scientific research, had the satisfaction of learning, just before his death, that a sum had been voted both for the repair of the fossils and for their enclosure in two large glass cases The work is proceeding at once

An earthquake of moderate intensity was recorded at Kew Observatory on May 4 The first impulse was received at 4 h 46 m 22 s G M T The records indicate that the shock occurred at a distance of 4,500 miles and probably near the coast of British Columbia

At the anniversary meeting of the Royal Society of South Africa held at Cape Town on March 21, the following were elected officers for the year 1934 *President*, Dr A W Rogers, *Hon Treasurer* Prof L Crawford, *Hon General Secretary*, A J H Goodwin, *Hon Editor of Transactions* Prof R S Adamson, *Hon Librarian* Prof E Newbery

The following appointments in the Colonial Agricultural Service have recently been made by the Secretary of State for the Colonies Mr C H Burgess to be agricultural field officer, Federated Malay States, Mr J R E Hindson to be inspector of plants and produce, Gold Coast, Mr R K Kerkham to be agricultural officer, Uganda, Mr R W Kettlewell to be district agricultural officer, Nyasaland, Mr A E Moss to be inspector of plants and produce, Gold Coast, Mr E Williams to be superintendent of agriculture, Gambia, Mr F M Bain, formerly inspector, plant protection ordinance, Trinidad, to be agricultural officer, Trinidad, Mr T McEwan, formerly senior agricultural research officer, Northern Rhodesia, to be agricultural officer, Uganda

The Dorothy Temple Cross Research Fellowships in Tuberculosis of the value of at least £350 each for one year for the academic year 1934–35 will shortly be awarded by the Medical Research Council, and applications should be lodged with the Council not later than June 1 The object of these fellowships is to give special opportunities for study and research to persons intending to devote themselves to the advancement by teaching or research of curative or preventive treatment of tuberculosis in all or any of its forms The fellowships will preferably be awarded to candidates who wish to make their studies or inquiries outside the borders of Great Britain It may also be possible to award a Senior Fellowship of considerably greater value to a specially well qualified candidate wishing to undertake an intensive study of some particular problem of tuberculosis at a chosen centre of work in another country Particulars are obtainable from the Secretary Medical Research Council, 38 Old Queen Street, Westminster, S W 1

Applications are invited for the following appointments, on or before the dates mentioned —A lecturer in geography (woman) at Bingley Training College—The Education Officer, County Hall, Wakefield, Yorks (May 16) A teacher of domestic subjects at the National Society's Training College of Domestic Subjects, Berridge House, Fortune Green Road, London, N W 6—The Principal (May 21) A clinical biochemist at the Glasgow Royal Infirmary—The Superintendent, Royal Infirmary, Castle Street, Glasgow (May 21) A lecturer in experimental psychology at the University of St Andrews— The Secretary (May 24) An assistant lecturer in physics at University College Gower Street, London W C 1 —The Secretary (May 26) A fuel technologist to the Public Service Board of New South Wales— The Official Representative of the Government of New South Wales, Wellington House, 125, Strand W C 2 (May 31) A reader in dyeing and printing, a reader in chemical engineering a lecturer in experimental dyeing, a lecturer in industrial and tinctorial chemistry, and a lecturer in fuel technology at the University of Bombay—The Registrar (May 31) A lecturer in economics, an assistant lecturer in pharmaceutical chemistry, a demonstrator in mechanical engineering, and a demonstrator in electrical engineering at University College, Nottingham—The Registrar (June 1) An intelligence officer in the Engineering and Metals Section of the Department of Overseas Trade—The Chief Establishment Officer, Department of Overseas Trade, 35, Old Queen Street, Westminster, S W 1 (May 31) Two Robert Blair fellows in applied science or technology—The Education Officer (T 3), The County Hall, S E 1 (June 1) A junior scientific officer (chemist) in the Department of Scientific and Industrial Research—The Secretary, 16, Old Queen Street, London, S W 1 (June 2) An assistant lecturer in mechanical engineering at the Manchester Municipal College of Technology—The Registrar (June 4) A lecturer in geography at Truro Training College— The Principal Assistant keepers in zoology, entomology and botany at the British Museum (Natural History)—The Secretary, British Museum (Natural History), London, S W 7 A professor of botany at the University of Reading—The Registrar

Mass of the Neutron

THE mass of the neutron has been calculated by Chadwick on the assumption that the neutrons of boron are emitted by the isotope $^{11}_{5}\mathrm{B}$, according to the nuclear reaction

$$^{11}_{5}\mathrm{B} + ^{4}_{2}\mathrm{He} = ^{14}_{7}\mathrm{N} + ^{1}_{0}n$$

Using the exact masses of $^{11}_{5}\mathrm{B}$, $^{4}_{2}\mathrm{He}$ and $^{14}_{7}\mathrm{N}$ and the maximum energy of the neutron excited by the α rays of polonium, one may calculate for the neutron a mass 1 0068 (taking $^{16}\mathrm{O} = 16$) [1]

We have suggested[2] that the emission of the neutron of boron is due to the isotope $^{10}_{5}\mathrm{B}$ and not to $^{11}_{5}\mathrm{B}$ The nucleus $^{10}_{5}\mathrm{B}$ can suffer two kinds of transmutation under the action of the α particles of polonium one with the emission of a proton, one with the emission of a neutron and a positive electron, according to the equations

$$^{10}_{5}\mathrm{B} + ^{4}_{2}\mathrm{He} = ^{13}_{6}\mathrm{C} + ^{1}_{1}\mathrm{H}$$

$$^{10}_{5}\mathrm{B} + ^{4}_{2}\mathrm{He} = ^{12}_{6}\mathrm{C} + ^{1}_{0}n + \overset{+}{\varepsilon}$$

Our latest experiments on the creation of new radio elements have confirmed our interpretation of the transmutation of boron Similar reactions are observed with the nucleus $^{27}_{13}\mathrm{Al}$ and with $^{24}_{12}\mathrm{Mg}$ The reactions can be divided in two steps

$$^{10}_{5}\mathrm{B} + ^{4}_{2}\mathrm{He} \quad ^{13}_{7}\mathrm{N} + ^{1}_{0}n \qquad ^{13}_{7}\mathrm{N} = ^{13}_{6}\mathrm{C} + \overset{+}{\varepsilon}$$

$$^{27}_{12}\mathrm{Mg} + ^{4}_{2}\mathrm{He} - ^{27}_{14}\mathrm{Si} + ^{1}_{0}n \qquad ^{27}_{14}\mathrm{Si} = ^{27}_{13}\mathrm{Al} + \varepsilon$$

$$^{27}_{13}\mathrm{Al} + ^{4}_{2}\mathrm{He} = ^{30}_{15}\mathrm{P} + ^{1}_{0}n \qquad ^{30}_{15}\mathrm{P} - ^{30}_{14}\mathrm{Si} + \varepsilon$$

$^{13}_{7}\mathrm{N}$, $^{27}_{14}\mathrm{Si}$, $^{30}_{15}\mathrm{P}$ being unstable nuclei that disintegrate with the emission of positrons

The complete reactions, with the masses and energy of all the particles are for the two modes of transmutation of boron

$$^{10}_{5}\mathrm{B} + ^{4}_{2}\mathrm{He} + W_{\alpha} = ^{13}_{6}\mathrm{C} + ^{1}_{1}\mathrm{H} + W_{H} + W_{R}$$

$$^{10}_{5}\mathrm{B} + ^{4}_{2}\mathrm{He} + W_{\alpha} = ^{12}_{6}\mathrm{C} + ^{1}_{0}n + \overset{+}{\varepsilon} + W_{n} + W_{\varepsilon} + W'_{R},$$

where W_{α}, W_{H}, W_{n}, W_{ε}, W_{R}, W'_{R} are the energies of the α particle and the corresponding energies of the ejected particles and of the recoil atoms in the reactions Subtracting the first of these equations from the second gives

$$^{1}_{0}n = \text{mass of proton} - \text{mass of positron} + Q,$$

where $Q = W_{H} + W_{R} - W_{n} - W'_{R} - W_{\varepsilon}$

One gets exactly the same equation using the transmutations of aluminium and magnesium

Thus these equations enable us to calculate the mass of neutron without using the exact masses of any nucleus, except the proton

According to our most recent measurements, the positrons emitted by the new radio elements form a continuous spectrum of maximum energy 1 5 × 10⁶ e v for $^{13}_{7}\mathrm{N}$, 3 × 10⁶ e v for $^{30}_{15}\mathrm{P}$ and approximately 1 5 × 10⁶ e v for $^{27}_{14}\mathrm{Si}$ The emission of positrons is probably accompanied by the emission of neutrinos, but if the positrons have their maximum energy the neutrinos will have a very small energy, the most recent hypotheses on the nature of this particle admits of a mass which is zero, or very small So we need not take this particle into account in the calculations The energy of the recoil atom in the disintegration with emission of a positron is negligible

For the irradiation with the α rays of polonium we have the following numerical values for the energies (expressed in 10^6 e v)

	W_H	W_R	W_n	W'_R	W_ε	Q (10^6 e v)	Q in units of mass
B	8 05	0 23	3 3	0 59	1 5	+ 2 89	0 0031
Al	7 56	0 11	2	0 33	3 0	+ 2 34	0 0025
Mg	4 82*	0 21	1	0 48	1 5	+ 2 05	0 0022

One gets for the mass of neutron three values 1 0098, 1 0092, 1 0089 These values agree approximately Yet the first, deduced from boron, is the most precise The energies of the neutrons of aluminium and magnesium and the energy of the positrons of magnesium are not well known

From considerations on the stability of the nucleus $^{9}_{4}\mathrm{Be}$, the mass of the neutron should have a minimum value 1 0107 But an error of 0 001 in the determination of the mass of Be seems quite possible

We may adopt for the mass of the neutron a value 1 010, in which the error probably does not exceed 0 0005

With the mass 1 010 for the neutron, the maximum energy of the neutron ejected from beryllium by α particles from polonium should be about 9 × 10⁶ e v The emission of slow neutrons when lithium is bombarded with α particles from polonium, according to the reaction $^{7}_{3}\mathrm{Li} + ^{4}_{2}\mathrm{He} = ^{10}_{5}\mathrm{B} + ^{1}_{0}n$, cannot be explained unless the mass adopted for $^{10}_{5}\mathrm{B}$ is too great namely, by about 0 003

If atomic nuclei contain only protons and neutrons, then the β emission might be the consequence of the transformation of a neutron into a proton inside the nucleus, with the ejection of the negative electron and a neutrino, as has been suggested by several authors The inverse processes would also be possible transformation of a proton into a neutron with the ejection of a positron and a neutrino

With the mass 1 010 for the neutron, the energy liberated in the transformation neutron → proton + $\overset{-}{\varepsilon}$ is 2 1 × 10⁶ e v , the energy absorbed in the transformation proton → neutron + $\overset{+}{\varepsilon}$ is 3 1 × 10⁶ e v

Induced Radioactivity of Sodium and Phosphorus

IN view of the discovery of induced radioactivity' by F Joliot[1], I have investigated several other elements with an apparatus specially designed for the study of activities with a very short lifetime The substance to be investigated was attached to the end of a swinging arm, which made it possible to shift the substance within half a second from the α ray source, consisting of about 1 millicurie of thorium B + C to a Geiger Muller counter with a window of 0 05 mm copper foil

I have found that both sodium and phosphorus become active after α ray bombardment Three different sodium compounds (NaCl, NaF, $Na_2C_2O_4$) have been investigated, they all showed a fairly strong activity, dying off very quickly The half value period has been determined by recording the impulses on a rotating drum the whole decay curve being recorded 21 times The half value period was found to be 7 ± 1 seconds Phosphorus (elementary red phosphorus) showed a very much longer lifetime The half value period was found to be 40 ± 5 minutes

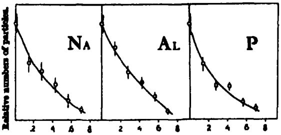

FIG 1

The initial activity of phosphorus was about one sixth that of aluminium The initial activity of pure sodium under the same conditions was estimated from the composition of the salts to be about half that of aluminium

The sign of the particles emitted by the substances was determined by deflection in a magnetic field Both sodium and phosphorus were found to emit mainly positive electrons In the case of sodium no negative particles have been detected, there cannot be more than one fifth of the positives if any In the case of phosphorus the results are not quite so definite, anyhow the negative particles cannot be more than one third of the positives

Some information about the energy of the particles was obtained by putting copper foils between the substance and the window of the counter For a better comparison the same has been done with the particles emitted by aluminium The three absorption curves are given in Fig 1, the mean statistical error being indicated by the vertical lines The range of the particles can be extrapolated to be about 0 8 gm /cm ^{2} of copper, corresponding to an energy of 1 8 × 10^6 e v, for all three elements

The nuclear reactions leading to the creation of these new active elements are very probably analogous to the production of radio phosphorus by bombarding aluminium In that case, the reaction is generally assumed to be ${}_{13}\mathrm{Al}^{27} + \alpha = {}_{15}\mathrm{P}^{30}$ + neutron, the ${}_{15}\mathrm{P}^{30}$ disintegrating after a time according to the reaction ${}_{15}\mathrm{P}^{30} = {}_{14}\mathrm{Si}^{30}$ + positron So for sodium and phosphorus the reactions would be ${}_{11}\mathrm{Na}^{23} + \alpha = {}_{13}\mathrm{Al}^{26}$ + neutron and ${}_{15}\mathrm{P}^{31} + \alpha = {}_{17}\mathrm{Cl}^{34}$ + neutron respectively In the last case, this view was confirmed by the chemical separation of the active chlorine The active phosphorus was burned, the products of combustion dissolved in caustic soda The solution was acidified with nitric acid, a trace of ammonium chloride added and then excess of silver nitrate The silver chloride filtered off and washed on a small disc of filter paper, was found to contain more than 50 per cent of the original activity, showing the same time decay

By extrapolating the series of odd elements ${}_{15}\mathrm{P}^{31}$, ${}_{13}\mathrm{Al}^{27}$, ${}_{11}\mathrm{Na}^{23}$, all of which show induced activity, one would anticipate that ${}_{9}\mathrm{F}^{19}$ would show it too, especially since fluorine is known to emit neutrons under α ray bombardment On the other hand, the extrapolation of the periods 40 min 3 min 7 sec, leads to a very short life for the hypothetical activity produced in fluorine I have tested calcium fluoride in my apparatus, but have not been able to find definite evidence of an activity

β-Emission of Positive Electrons

THE artificial production of radioactive isotopes recently discovered[1] has to be brought into connexion with the theoretical treatment of the β type of radioactive transformation[2] It is easily seen that the formulæ given for the β decay of heavy elements apply to the emission of positive electrons by simply changing the sign of the charges involved We have calculated the continuous energy spectra to be expected from N^{13} both according to the theory developed some time ago by ourselves and according to the assumption that a so called neutrino is emitted simultaneously with the electron The curves obtained in this way are very similar and may be represented by Fig 1, which has been drawn for a special case It seems to us that it will be scarcely possible to distinguish between those two theories by measuring the shape of the energy spectrum

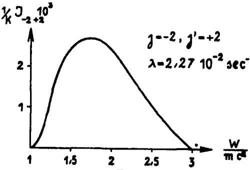

FIG 1

The decay constant however, resulting from the extrapolation of the values known for the heavy radioactive β bodies fits very nicely the order of magnitude of the value of several minutes actually observed (A more exact comparison cannot be made unless the upper energy limit of the continuous energy spectrum has been determined) This fact seems to confirm the view previously taken by us, that the extremely long life period of the lighter β bodies (potassium and rubidium) should not be compared with that of the other β active substances The extremely high values of the decay constants of these elements have evidently to be explained by a more complicated mechanism, possibly by a double process in which two electrons leave the nucleus simultaneously

Slip-bands and Twin-like Structures in Crystals

THE β-constituent of the copper zinc alloy system containing about 48 50 per cent zinc and having a cubic body-centred crystal lattice does not readily show slip bands when the crystals are distorted[1] On the other hand structures resembling twins have been described[2] v Göler and Sachs[3] found slip bands on some crystals only and identified them approximately with traces of dodecahedral planes {110} I have recently confirmed the occurrence of slip bands agreeing with the traces of {110} planes in a number of crystals (Fig 1) and in some cases the distortion can be accounted for completely by slip on one of these planes and in a direction parallel to the normal of an octahedral plane [111] More often the distortion is more complicated and other dodecahedral planes are involved In these circumstances the slip bands do not represent crystal planes but relics on the surface of the original traces of planes

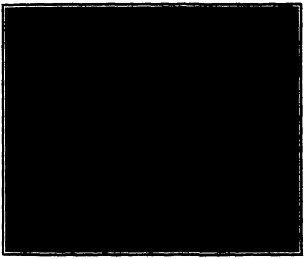

FIG 1 Two deformed β brass crystals showing slip-bands and twin like structure near boundary × 100

Twin like structures are produced when slip takes place on two planes equally inclined to the axis (in a tensile test) in different parts of the same crystal This frequently occurs if the axis lies in a {100} plane for example when the uniting plane coincides with this plane at the beginning of the distortion but soon ceases to do so as deformation proceeds These structures persist when the crystal is repolished and re-etched and resemble lamellar twinning if there are many of them

When the crystals are rolled they fracture with an almost perfect cleavage parallel with one or more {110} plane The separation occurs with a loud crack

Intensity Measurements in the First Positive Bands of Nitrogen

WE have recently measured the intensities of several of the first positive bands of nitrogen using the method of photographic photometry As sources the afterglow of active nitrogen and a high frequency electrodeless discharge in nitrogen at a low pressure have been used The figures in the second and third columns below are proportional to the energy radiated per second by the gas due to the various vibrational transitions indicated

Band v – v	Intensity		Intensity ratio H F discharge/Afterglow
	H F discharge	Afterglow	
10-6	294	128	2 30
10-7	245	99	2 48
11-6	68	102	0 67
11 7	300	520	0 58
11 8	159	270	0 59
12 7	74 5	59	1 26
12 8	244	190	1 28
12 9	151	55 5	2 72

If the probability of a transition occurring between two levels is independent of conditions of excitation it is evident that the figures in the last column must be constant for bands having a common value of v Our results show that this is the case for $v = 10$ and 11 to within 15 per cent but does not hold for bands having $v = 12$ There is however close superposition of the 4 0 band on the 12 9 band which would have the effect of increasing the apparent intensity of the 12 9 band In the afterglow of active nitrogen the progression having v 4 is very weak but in the high frequency discharge (and in direct current discharge) it is of appreciable strength These facts would be sufficient to account for the variation noted in the table

Preliminary measurements with direct current excitation give results in which the intensity ratio H F discharge/D C discharge is nearly constant within each progression examined

Influence of Oxygen, Sulphur Dioxide and Moisture on the Homogeneous Combination of Hydrogen with Sulphur

PREVIOUSLY[1] we have shown that minute traces of oxygen lead to an apparent increase in the rate of formation of hydrogen sulphide from its elements as judged by the iodine titre of the resulting gaseous products The increase was ascribed to a catalysis by oxygen though we pointed out that the effect of so minute a quantity of oxygen is remarkable and unexpected The subject has been systematically investigated using hydrogen containing known concentrations of oxygen ranging from 0 06 to 7 per cent by volume at temperatures between 290° and 343° C The method adopted a static one[2] was carried out in Pyrex bulbs containing quantities of sulphur which, whilst always sufficient to combine with the oxygen present several times over, were yet insufficient to leave any liquid at the temperature of the reaction The products consisted of a mixture of sulphur dioxide and hydrogen sulphide together with the excess of sulphur and hydrogen The amount of each compound was ascertained by an iodometric titration followed by a gravimetric estimation

The results showed that the whole of the oxygen goes to sulphur dioxide in the first few minutes, and that, thereafter the hydrogen proceeds to react with the remaining sulphur at precisely the anticipated velocity for hydrogen alone In unpacked bulbs, there is no detectable reaction between the sulphur dioxide and the hydrogen sulphide so formed in one hour This shows that neither free oxygen nor sulphur dioxide affect the velocity of the hydrogen sulphur reaction and is contrary to the observations of Norrish and Rideal[3] who, using a dynamic method, found that oxygen had a strong poisoning effect in the gaseous reaction between hydrogen and sulphur at all temperatures

In packed bulbs some of the sulphur dioxide and the hydrogen sulphide reacts thus $2H_2S + SO_2 \quad 2H_2O + 3S$ (specific mechanism not implied) but only at the glass surface and hence to an undetectably small extent in unpacked bulbs The findings of Taylor and Wesley[4], who showed this reaction to be heterogeneous by a dynamic method are thus confirmed under static conditions

Since steam is formed in packed bulbs, evidently moisture as well as sulphur dioxide, is without effect on the hydrogen sulphur reaction In confirmation of this, hydrogen containing 2 per cent of moisture by volume has been found to give identical velocities with those already established for hydrogen which had been slowly passed over a length of phosphoric oxide

The Theory of Two Factors versus the Sampling Theory of Mental Ability

THE accompanying diagram (Fig 1) gives a graphic representation of the extent to which an observed frequency distribution of 22,712 tetrad-differences (of the form $r_{13}r_{24} - r_{23}r_{14}$) derived from 170 correlation coefficients between 19 non-overlapping mental tests[1] approximates, on one hand, to the theoretical distribution to be expected according to the Two Factor Theory of Prof C Spearman and, on the other hand, to the theoretical distribution to be expected according to the Sampling Theory of Prof Godfrey H Thomson

According to the Two Factor Theory[2], the abilities measured by the mental tests are divisible into two factors each, one being common to all (the general factor, *g*), while the other is in each case specific and independent (the specific factor, *s*)

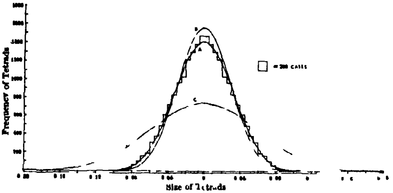

FIG 1 A Best fitting curve (Type IIa Pearson curve) to observed distribution of tetrads with equation

$$y = 1412\left(1 - \frac{x^2}{0\ 17234^2}\right)^{11\ 000} \quad \sigma_t = 0\ 041289$$

B Theoretical curve (Type IIa) to be expected assuming the truth of the Two Factor Theory (Spearman) with equation

$$y = 1563\left(1 - \frac{x^2}{0\ 1557^2}\right)^{9\ 000} \quad \sigma_t = 0\ 02827 \pm 0\ 0025866$$

C Theoretical curve (Type IIa) to be expected assuming the truth of the Sampling Theory (Godfrey Thomson) with equation

$$y = 749\left(1 - \frac{x^2}{0\ 3248^2}\right)^{11\ 000} \quad \sigma_t = 0\ 059 \text{ (allowing also for random sampling)}$$

According to the Sampling Theory[3], any one mental ability is due to the operation of a certain set of factors, another ability to another set, and so on, and these sets may overlap in any manner On this theory, if we assume a number of variable elementary factors, *N*, we can get values for *N* from the observed values of r (0 413) and σ_r (0 087) of our table of 170 correlation coefficients, on certain assumptions as to form of distribution of the factors and of their proportions entering into each ability

Mr John Mackie[4] has given the most generalised mathematical expression, up to date, for the Sampling Theory, and accepting certain of his formulæ as those most likely to apply to our investigation, we have

$$\sigma_r = \sqrt{1 - \left(\frac{2}{\pi}\right)^2} \Big/ \sqrt{N} \qquad \text{(p 32)}$$

that is, $0\ 087 = 0\ 77/\sqrt{N}$, giving $N = 77$

$$\text{and } \sigma_t = 0\ 463/\sqrt{N} \qquad \text{(p 31)}$$
$$= 0\ 052$$

The same value of σ_t follows from $r = 0\ 413$, by the formulæ

$$r = \frac{2}{\pi}\sqrt{p_1 p_2} = \frac{2}{\pi} p \qquad \text{(p 33)}$$
$$\text{and } \sigma_t = 2p(1 - p)/\sqrt{N} \qquad \text{(p 34)}$$

But this value of σ_t does not allow for random sampling (of the population) Allowing for this kind of sampling, the correct value is

$$\sigma_t = \sqrt{0\ 052^2 + 0\ 028^2} \quad \text{(0 028 is the } \bar{\sigma}_t \text{ of the Two Factor Theory)}$$
$$= 0\ 059$$

As a Type II*a* Pearson curve was found to be the best fitting curve for the observed distribution of tetrads with $\sigma_t = 0\ 031$ (curve *A*) similar Pearson curves have been drawn corresponding to the Two Factor Theory with $\sigma_t = 0\ 028 \pm 0\ 0026$ (curve *B*) and to the Sampling Theory with $\sigma_t = 0\ 059$ (curve *C*) It can be seen by inspection which of the two curves *B* or *C* approximates more to curve *A*

Further evidence against the applicability of the Sampling Theory to our data is given if we *assume* the truth of this theory (with Mackie s equations) and set out from the *observed* value of σ_t that is 0 031

$$\text{Since } \sigma_t = 0\ 463/\sqrt{N}$$
$$\sqrt{N} - 15 \text{ and } N = 225$$

Water Supplies and Emergency Legislation

WHEN we wish to determine the relation between the rain falling on an area and the volume of water delivered by the stream draining that area we are faced with a problem as yet unsolved The geological physical and meteorological conditions of river catchment basins are so varied that a search for a mathematical expression connecting yield from rainfall appears to be in vain

The simplest and most accurate method for such determination is as suggested in the leading article in NATURE of April 28 by the actual measurement of stream flow for a considerable number of years so as to ascertain the mean the maximum and the minimum flow that may be expected and also the variation of stream flow during the seasons of the year Comparing the results so obtained with the rainfall during those years we may be able to deduce with some reasonable accuracy stream flow in years in which rainfall records are available and stream flow gaugings are not

Observation of stream flow in Great Britain have been neglected and the same remark applies to observation of water levels in our wells Some years ago the British Association laid down a series of questions in regard to wells which appear to have been lost sight of It is possible that the limited funds allotted for investigations of this nature curtailed the information collected

The heavy rains of 1927 the disaster of January 1928 and the following wet years caused the country to be more concerned with floods and arterial drainage than with drought leading to the appointment of the Royal Commission of 1927 and the passing of the Drainage Act of 1930 and so to the formation of Catchment Boards with the result that schemes for widening and deepening our rivers and carrying off the rainfall as quickly as possible are under consideration

Speculative building on riparian lands subject in former years to flooding at very long intervals are now more frequently flooded due to the increased flow from drainage of lands permeable areas and arterial roads and this has increased the demand for a more rapid carrying away of flow due to rainfall

The problem that now faces the country is the preservation of our springs Most of our rivers derive their dry weather flow from springs the only source of supply of which is the percolation of our winter rains to the ground water plane of saturation and instead of widening and deepening our rivers to pass off extraordinary floods quickly the flood water should be allowed to spill over the river margins so that as the flood slowly subsides the water is enabled to percolate into the subsoil One other suggestion I would make is a return to Mr Joseph Elkington s sink hole drainage That is instead of passing off rain water from whatever sources it may be received into streams and thus swell our rivers it is passed into soakage pits or absorbing wells placed at suitable intervals and sunk to permeable areas and thus to pass the rainfall to ground storage

The Catchment Boards I would suggest should now confine their activities to the measurement of stream flow and its correlation with rainfall to carry out the requirements of the British Association in regard to riparian lands subject to periodic flooding so as to reserve them for pasture or agriculture and to prevent speculative building thereon

Factors Controlling Moulting and Metamorphosis in an Insect

IN the blood sucking bug *Rhodnius prolixus* moulting occurs at a definite interval after feeding only one meal being necessary in each stage The morphological changes at moulting are relatively slight save at the fifth moult when the insect becomes adult[1] It is therefore convenient (without prejudice to questions of homology) to refer to this final moult as metamorphosis In this last stage the interval between feeding and moulting averages twenty eight days If its head is removed soon after feeding the insect will not moult—although some of these headless individuals have remained alive more than eleven months But there is a critical period about seven days after feeding after which moulting is no longer prevented by decapitation If the blood from an insect decapitated *after* this critical period is allowed to circulate in an insect decapitated *before* this period *the latter is caused to moult* Clearly a moulting hormone is present and it is probably secreted in the head Of the organs in the head the only one which shows distinct changes during this period is the corpus allatum the cells of which swell up to a maximum at about the seventh day after feeding and then diminish Perhaps this is the source of the moulting hormone—though the evidence on this point is still incomplete

Similar results have been obtained with the earlier nymphs But if the blood from a 5th or final nymph decapitated *after* the critical period is allowed to circulate in a 4th nymph decapitated *before* this period, the latter shows a premature 'metamorphosis' and develops adult characters Two explanations of this result are possible either (*a*) the moulting hormone of the 5th nymph differs from the moulting hormone of the earlier nymphs , or (*b*) the hormone is always the same, but the earlier nymphs produce in addition an inhibitory hormone which restrains metamorphosis Of these alternatives the second appears to be correct For if the 4th, 3rd, 2nd, even the 1st nymphs are merely decapitated around the critical period', a certain number of them suffer a precocious metamorphosis' and develop into diminutive adults , while others show intermediate characters (prothetely) —due, perhaps, to the varying quantity of the inhibitory factor present in the blood at the time of decapitation

Two factors, therefore, seem to be concerned in the growth of *Rhodnius* a factor initiating growth or moulting, and a factor inhibiting 'metamorphosis' —both probably secreted in the head, and perhaps in the corpus allatum These results, which will shortly be published in full, confirm and extend the well known conclusions of Kopeć[2]

Spontaneous Crossing-over between *X*- and *Y*-Chromosomes in *Drosophila melanogaster*

MULLER and Painter[1] showed that more than one third of the *X* chromosome is almost inert genetically and corresponds to a section of the *Y*, and Friesen[2] obtained crossing over of autosomal genes in males by exposure to X rays It therefore seemed worth while investigating whether crossing over takes place between the *X* and *Y* chromosomes in the male during normal meiosis The gene under investigation, *bobbed* (shorter and finer bristles on the thorax), is the only one so far located both in the inert region and the *Y* chromosome

Males containing the mutant gene *bb* (bobbed) in their *Y* chromosome and its normal allelomorph in their *X* chromosome were crossed with bar bobbed females with attached *X* chromosomes carrying *Bbb* (bar eye) and a *Y* carrying *bb* By this method every change taking place in either *bb* locus in the male can be detected

The result of the cross was

	Expected flies		Exceptional flies	
Phenotype	*Bbb*♀	normal♂	*B*+*bb*♀	*bb*♂
	422	566	4	5

The exceptional *B*+*bb* females (bar, non bobbed) and *bb* males (non bar, bobbed) could have arisen either by crossing-over or by mutation both of normal to *bb* in the *X* chromosome, and of *bb* to normal in the *Y* chromosome The *B*+*bb* females could not have arisen by detachment of one of the attached *X* chromosomes since they were homozygous for bar eye The hypothesis of mutation seems to be excluded by the high frequency of the exceptions

The possibility of spontaneous crossing-over in the males has been suggested by Stern's[3] discovery of translocation of parts of the *Y* to the *X*-, and Darlington's[4] description of cytological conditions in the spermatogenesis of *Drosophila pseudo-obscura*, which makes the occurrence of crossing-over quite possible

The Attitude of the German Government towards Science

PROF STARK'S letter in NATURE of April 21 may not prove convincing to all its readers The fact that non Aryans' have been expelled from other posts does not necessarily justify their expulsion from scientific positions unless the premise that 'two blacks make a white' has first been conceded

It is difficult also to reconcile his assertion that scientific research is perfectly free in Germany with the reported speeches of such officials as the rector of University of Frankfort, who is alleged[1] to have said Nowadays the task of the universities is not to cultivate objective science, but soldier like, militant science, and their foremost task is to form the will and character of their students" This is not an isolated example of the attack on objectivity, on, in plain English, truth, which appears to be taking place in modern Germany For that reason many British scientists feel that criticism of the present German government may not merely be of value to their expelled colleagues, but also to those 'Aryan Germans who are still trying, under very difficult conditions, to uphold their country's great tradition of objective science

Psychology of Musical Experience

I HAVE long been impressed by a passage about Lagrange, the prince of mathematicians, in Thomas Young's biographical sketch "In the midst of the most brilliant societies he was generally absorbed in his own reflections and especially when there was music, in which he delighted, not so much for any exquisite pleasure that he received from it, as because, after the first three or four bars, it regularly lulled him into a train of abstract thought, and he heard no more of the performance, except as a sort of accompaniment assisting the march of his most difficult investigations, which he thus pursued with comfort and convenience "

I now notice that it correlates rather closely with a remark of Darwin, the prince of naturalists, in the well known passage in his autobiography where, after describing the atrophy of his tastes for literature and painting and music, he proceeds "Music generally sets me thinking too energetically on what I have been at work on, instead of giving me pleasure "

Research Items

Prehistoric East Anglia Dr Cyril Fox, in his presidential address to the Prehistoric Society of East Anglia for 1933, which is published in full in the *Proceedings* of the Society, vol 7, pt 2, discusses the implications of a series of maps showing cultural distributions from neolithic times to the iron age, that is, from about 2300 B C to A D 50 He points out initially that in the Lowland area of Great Britain, of which East Anglia is a part, human distribution is determined by the character of the soil Hence East Anglia is divided into three zones, of which two a western and an eastern, suitable for the habitation of early man, are separated by an unsuitable area, a plateau, forming the East Anglian watershed, which is extended southward to the Thames valley by the exposure of the London clay In each successive period, therefore, the distribution maps show that the area of closest settlement was within the inner curve of the clay covered watershed, with a second area of density in the lower Thames valley and estuary A shift of the population on the chalk belt in the course of ages was accompanied by a like southward movement on the coastal belt, as the estuarine trade sought the shortest route to its markets in the centres of denser population through the valleys which penetrated the plateau in the direction of the settlement area on its western side Changes in distribution of population on the chalk belt in the later periods indicate the opening up of fertile but less easily worked, lands by the Iron Age Celtic tribes, to whom the Belgæ found themselves opposed and against whom they erected their great system of earthworks, when they had occupied the hitherto unexploited land around St Albans, which they had reached from the Thames valley and not from the east coast Differences in type of distribution bring out clearly the distinction between the products of a locally developed culture, of objects imported by trade, and of those introduced by invasion The series of maps strikingly confirms the reliability of the available data as an index—though an incomplete reflection—of the life of the dwellers in the region, showing where it was vigorous, where it was sluggish, and where almost entirely absent

Mass Physiology in Animals W C Allee (*Biol Rev*, 9 Pt 1, 1934), in reviewing recent work on mass physiology, remarks that analysis of the reactions leading to the formation of aggregations in Nature, or in the laboratory, has scarcely proceeded beyond the recognition that much of such behaviour is innate, although recent evidence indicates that a part of the schooling behaviour of the fish *Ameiurus* is acquired rather than inherited It is easy to demonstrate that overcrowding lessens the rate of growth of organisms, evidence is presented that undercrowding (for example, in mealworms, fishes, mice) frequently has the same effect The results from aggregation upon the rate of oxygen consumption vary with different animals, thus, for example, goldfishes in small groups use less oxygen than when isolated, but with the more closely schooling *Ameiurus* opposite results are reported Groups of animals are able to afford protection to their members if exposed to toxic conditions due to the absence of accustomed salts (as the marine flat worm *Procerodes* does when placed in fresh water) or to the presence of toxic substances such as colloidal silver The amount of protection has been measured for some examples and the protective mechanisms are discussed The transition from parthenogenetic to sexual reproduction in certain Crustacea (Cladocera) has been shown to result from overcrowding The effect of numbers present upon the rate of learning differs with different animals and even in the same animals with different problems, thus, fishes learn to run a simple maze more rapidly if in groups than if isolated, but they learn less readily to jump for a bit of worm held just above the water level Cockroaches learn to run a simple maze more slowly if more than one is present in the maze at the same time Groups of birds show a fairly definite flock organisation which may or may not be related to active leadership of the flock The whole range of mass physiology has been presented with the thought that it forms a large part of the background for social life'

New Snails from Hawaii Mr C Montague Cooke, jun in his paper New Species of Amastridæ ' (*Bernice P Bishop Museum, Occasional Papers*, 10, No 6, 1933) describes many new members of this interesting genus, which is peculiar to the islands of the Hawaii group, usually living on or under trees or under wood and stones These snails are viviparous and bear embryos of a fair size, the embryonic whorls having distinct sculpture One specimen of *Amastra* (*Metamastra*) *gulickiana dichroma*, new sub species, although not quite fully grown contained an embryo of about two and a half whorls Many of the shells, however, were found dead and in one locality, East Maui, Kula, near the division between the lands of Keokea and Kamaole where there are the last remnants of a native forest of a few decades ago, there were numbers of dead shells of several species and genera scattered among the loose surface stones Under a single stone about two or three quarts of the richest fossiliferous earth was uncovered From this mass of earth about 1,300 whole or nearly whole shells were picked out with representatives of about 70 species belonging to 23 genera including a new species *Amastra inopinata* Undoubtedly this region was inhabited by a rich land snail faûna some time within the last hundred years A number of these species must be entirely extinct as no native forest area is located within several miles The shape of the various forms varies enormously, some of the shells flat and almost like a *Planorbis* others *Achatina* shaped, some sinistral

Japanese Decapods A valuable monograph on the distribution of decapod crustaceans inhabiting the continental shelf around Japan, chiefly based upon materials collected by the S S *Sôyô Maru*, during the years 1923–30, by Yu Yokoya (*J Coll Agric, Tokyo Imperial University*, 12, No 1, 1933) gives a very good idea of what is common and what is rare in this area, all the records are given with sex and egg (if any) included, so that the breeding seasons are also shown The extensive material from 658 stations was collected during the biological survey of the continental shelf of Japan, surrounding Honsyû, Sikoku and Kyûsyû, by the surveying ship of the Imperial Fishery Experimental Station of Tokyo 292 species of decapods are recorded, 52 being new to science, and there are 33 new records for Japanese waters, whilst 3 new genera are proposed. Most of the stations were of 100–400 metres depth, therefore few shallow water forms are included. Some species have a northerly distribution extending from central Japan as far as the Bering Sea, Alaska and the west of America, others a southerly distribution to the Malay Archipelago, Indian Ocean and Australia. The northern species were collected mainly from the west side of Japan, the southern species mainly from the east, but there are some notable exceptions and the subject is a complicated one which is discussed together with the position of the currents. Two main currents are well known, the warm current, the 'Kuro siwo", sweeping the south east coast from the East Indian region and turning eastward, and the cold current, the "Oya Siwo", entering the North Pacific by the Bering Strait, principally deflected along the western side.

Hydroids as Enemies of Fishes. E. W. Gudger (*Ann. Mag. Nat. Hist.*, 13, No. 74, Feb. 1934) remarks that the lower invertebrates are commonly thought of as food for fishes rather than as enemies—and so they are broadly speaking—but he brings together the recorded observations on *Hydra* and sessile colonial hydroids as fish eaters, beginning with those of Trembley (1744) who saw young roaches, about one third of an inch long, caught by the tentacles of *Hydra*, carried to the mouth and swallowed. Beardsley (1904) found the mortality among trout fry in the troughs of a hatchery at Leadville, Colorado, to be due to the presence of great numbers of *Hydra pallida* (130 per square inch in one trough) and a heavy mortality in the ponds of a trout hatchery in Germany was due to the presence of *Hydra fusca*. The author summarises the accounts of the attacks of *Polypodium* on the ovarian and free ova of the sturgeon of the Volga, of the colonial hydroid *Hydrichthys mirus* which has been found on sea fish off Rhode Island and was believed by Fewkes (1887) to be parasitic, of *H. boycei* described by Warren as parasitic on *Mugil* and other fish in South Africa, and lastly of a species of *Clytia* which fed on young angler fish (*Lophius*) in jars in the Plymouth Laboratory.

Parasites of the Hessian Fly. Miscellaneous Publication No. 174 of the U.S. Department of Agriculture (Dec. 1933) consists of a paper by Mr. A. B. Gahan on the serphoid and chalcidoid parasites of the Hessian fly in America. Some 41 species are clearly described and figured with very full synonomy and biological data. Since many of the species dealt with also occur in Europe, this work is one which is of importance to British and other extra American students of the parasitic Hymenoptera. Particular interest is attached to the species *Eupelmella* (*Eupelmus*) *vesicularis*, Retz., which appears to be one of the most polyphagic species of all the Chalcids, since its recorded hosts embrace no fewer than 68 species, belonging to six of the major orders of insects. This feature is all the more remarkable from the fact that the insect has greatly abbreviated wings and is incapable of flight. Five generations have been reared in a single season and males are unknown. Geographically it extends from the British Isles to Russia eastwards, and to Italy in the south. In North America it is likewise very widely distributed. Owing to its polyphagic habits, it appears to be of little economic value as a primary parasite. The most efficient parasite in the biological control of the Hessian fly seems to be *Platygaster hiemalis*, Forbes and, in North America, it is practically the only species which attacks the autumn generation of that host.

Plant Tumours and Polyploidy. Dontcho Kostoff and James Kendall give some details (*Archiv Mikrobiologie*, 4, 487; 1933) of the cytology of tumourous growths produced in plants by various means—in some cases occurring generally over an interspecific hybrid, in others induced by injection of various chemical substances into the tissues or by injection with *Bacillus tumefaciens*. They regard these tumours as in all cases similar in construction, and in certain cases have been able to show that some of the cells in their neighbourhood have become either binucleate or multinucleate or polyploid. Such nuclear changes they attribute to an increased viscosity of the protoplasm, which makes the separation of the chromosomes more difficult after they have divided. From the neighbourhood of these tumours in some cases roots arise in which all the cells are polyploid or which have a chimæral structure as regards polyploid and normal nuclear apparatus. In other cases it was possible by cutting back shoots in the neighbourhood of tumours to obtain polyploid shoots and thus polyploid individuals could be separated and propagated. The authors are thus led to suggest that some of the various polyploid types that have been found growing naturally may have arisen as the result of cell disturbances produced by bacterial or other infection.

Earthquake Seawaves in North-East Japan. The Pacific coast of north eastern Japan, perhaps more than any other region in the world, is subject to the inrush of destructive *tunamis* or earthquake seawaves, the most recent examples being those of 1896 and 1933. Earlier *tunamis* along the same coast are described by Prof. A. Imamura (*Japan J. Astr. Geoph.*, 11, 79–93; 1934), who gives two reasons for their occurrence and destructiveness. Off this coast lies the deep Tuscarora trench, in which changes of level occur one after another in its bed, while the coast contains numerous V- or U-shaped bays opening towards the trench. Excluding *tunamis* less than 10 ft. in height, Prof. Imamura enumerates 15 from 869 until 1933, of which those of 869 and 1611 were the greatest. In the latter year, about 4,783 lives were lost, the height of the waves being 66 ft. as compared with 48 ft. in 1896 and 20 ft. in 1933. From 1611 until 1689, there were five *tunamis* along this coast. Then came a pause of one and a half centuries, followed by another epoch of activity culminating in the disaster of 1896. A few hours before the arrival of the *tunamis* in 1894, 1896 and 1933, large secondary undulations were observed in the water of the V-shaped inlets, suggesting that minor crustal deformations had occurred before the great movements that gave rise to the main *tunamis*.

Long Period Temperature Changes. In the *Monthly Weather Review* of September 1933 there is an interesting study of long period temperature trends by J. B. Kincer, that is carried back in certain cases to the latter part of the seventeenth century. A number of temperature records are analysed in a manner that has been found specially suitable for showing gradual changes The sum of the annual mean temperatures for the first twenty years of a record is obtained and is plotted as the first point on a curve additional points being obtained by subtracting the figure for the first year and adding that for the twenty first and so on In this method an occasional exceptional year or two has only a slight effect on the general run of the curve The analysis was applied to records in middle latitudes both in North America and Europe and to a few other parts of the world with rather striking results It appears that in middle latitudes there has been an upward trend since about the second quarter of the nineteenth century in spring autumn and winter the change being generally about 3 —a substantial figure when dealing with means for periods so long as twenty years The longest records are generally made in or very near to large towns and the possibility that the effect may be due to the growth of such towns and the consequent increase of the influence of artificial heating was considered A number of overlapping records at town and country stations in the same State in America showed such striking similarity that it was concluded that the effect is general and corresponds with a world wide change of climate

Absorption of 1 cm Waves Cleeton and Williams have successfully produced waves down to 1 1 cm in length by a vacuum tube oscillator and have made absorption measurements of these waves in ammonia gas (*Phys Rev* Feb 15) In accordance with a theory of Dennison the gas shows a strong absorption band in this region with a maximum absorption at λ 1 25 cm The oscillator used employs a special type of thermionic tube with a split anode The tube is placed in a strong magnetic field and the frequency of oscillation depends primarily on the time of transit of the electrons between cathode and anode The frequency may be varied over a small range by changing the magnetic field and the circuit voltages There is a small Lecher wire system inside the vacuum tube The spectrometer has an echelette grating of 18 elements and concave mirrors for focusing the waves which are detected by an untuned crystal detector at the focus of one of the mirrors

Electrical Measurement of Small Vibrations In the report of the Aeronautical Research Institute Tokyo Imperial University (No 103 Feb 1934) there is an interesting paper by J Obata S Morita and Y Yoshida describing an electrical method of measuring small vibrations and its application to the measurement of the vibrations of airscrew blades The electrical arrangement used comprises an electrical circuit containing a triode An oscillation with a frequency of about 600 000 cycles per second can be started in the circuit The displacement or vibration to be measured is made to produce a corresponding change in the anode current of the vacuum tube and this change is recorded by an oscillograph The novelty of the method is its extremely high sensitivity and the fact that there is no need to bring anything into contact with the moving body It is known that the vibration of the screw blades is one of the factors affecting the sound emitted The positions of the loops and nodes were determined for model airscrews and al[illegible]r an actual airscrew Oscillograms are shown for the vibrations of the blades for given striking and measuring points Fairly good agreement between the observed and the calculated values is obtained The most conspicuous feature observed in the records of the vibrations of blades is a remarkable beat which is especially prominent in the case of metallic airscrew models It was found that a slight change in the manner of clamping the airscrew model gave rise to marked changes in the number of beats produced per second The beat is undoubtedly produced by the coupled vibration of the two blades The degree of coupling is altered by changes in clamping It is interesting to note that when a four bladed airscrew model is vibrating then at the instant of the downward stroke of one of the blades the ends of the three remaining blades spring upwards

Multiplet Intensities in Stars Mr A D Thackeray has described an investigation of multiplet intensities in thirty stars in the late types *K5* and *M* (*Mon Not Roy Ast Soc* Dec 1933) His work which was carried out with the full spectrophotometric method confirms the results reported by workers at Yerkes Observatory who had announced that visual estimates of line intensities demonstrated the existence of anomalies in certain multiplets The relative intensities of the lines in a multiplet as they appear in a stellar spectrum do not agree with the theoretical values which have been confirmed by laboratory experiments The effect in solar multiplets was first reported by Minnaert and independently by Woolley A great deal of argument has been directed towards examining the cause of the anomaly so far without arriving at any conclusive result Thackeray discusses some of these arguments in the paper under review The Solar Physics Observatory Cambridge at which Thackeray carried out the work is to be congratulated on being amongst the first observatories to produce finished results of stellar spectrophotometry on narrow absorption lines with a slit spectrograph

Plate Efficiency in Fractionating Columns A paper was read by Mr A J V Underwood before a joint meeting of the Institutions of Chemical Engineers and Petroleum Technologists on March 21 dealing with the determination of plate efficiency in fractionating columns with complex mixtures The essence of the paper was an evaluation of individual plate efficiency which is generally taken as the ratio of change in composition of the vapour effected by a plate in the column to the change in composition which would result if the vapour after passing through the plate were in equilibrium with the liquid on it It was claimed that this efficiency could be calculated for each component of the mixture knowing the composition of the vapour below and above the plate the composition of the liquid on the plate and the composition of the vapour that would be in equilibrium with that liquid From the above it would seem that to obtain these data for any given fractionating column would involve numerous analyses of liquids and vapours in contact with every plate but the author showed that it is only necessary to determine liquid compositions leaving vapour compositions to be calculated by the use of material and thermal balances The assumption that an efficiency of the order of sixty to seventy five per cent is to be expected in practice was not supported by much available experimental data ; probably this efficiency is seldom attained and if it is on the low side then there is considerable scope for progress in modification of plate design

The Explanation of Supraconductivity

IT is customary to describe the supraconductive state of a metal by setting its specific electric conductivity σ equal to infinity I wish to direct attention to another possibility namely that the supraconductive state can be described much more adequately by setting equal to infinity the *dielectric constant* ε of the substance its conductivity σ remaining finite or even becoming equal to zero

The actual meaning of the new definition can be seen from a comparison of the mechanism of ordinary electric conduction (σ finite) and ordinary polarisation (ε finite) In the former case the electrons called free move *independently* the conduction current being constituted by a drift motion due to the action of an external electric field and superposed on the unperturbed random motion of the individual electrons In the second case the electrons called bound are displaced by the electric field simultaneously in the same direction the polarisation current being due to an orderly collective motion of all the electrons Under normal conditions the displacement of the electrons with regard to the respective atoms remains small compared with the interatomic distances this corresponds to a finite value of the dielectric constant The assumption that the latter becomes infinite means that under the action of an infinitesimal field the electrons are displaced simultaneously over finite distances each of them passing successively from an atom to the next one like a chain gliding over a toothed track

Such a collective motion of the bound electrons will constitute an electric current just as much as the individual motion of the free electrons but a *polarisation* current rather than a *conduction* one The electrostatic mutual action of the electrons moving collectively in a chain like way will stabilise them against the perturbing action of the heat motion of the crystal lattice which will result in the permanence of the polarisation current after the disappearance of the electric field by which it was started[1] This permanence which has been erroneously interpreted as corresponding to an infinite value of the specific conductivity must be interpreted in reality as corresponding to an *infinite value of the dielectric constant* Now how is it possible to explain the occurrence of such an infinite value ? This turns out to be a very simple matter the appropriate mechanism having been considered already by Hertzfeld who however failed to give it the correct interpretation Consider a chain of equally spaced atoms with a polarisation coefficient α This means that an isolated atom assumes under the action of an external field E an electric moment $p = \alpha E$ If the field E is acting in the direction of the chain then in computing the polarisation of a certain atom we must add to it the field E produced by all the other atoms in virtue of their induced electric moments All these moments being the same we get

$$E = \frac{2p}{a^3} 2 \sum_{n=1}^{\infty} \frac{1}{n^3} = 4\ 52 \frac{p}{a^3}$$

and consequently

$$p = \alpha \left(E + 4\ 52 \frac{p}{a^3} \right)$$

whence

$$p = \frac{\alpha E}{1 - 4\ 52\, \alpha / a^3} = \alpha\ E \qquad (1)$$

We thus see that with a finite value of α for an isolated atom an infinite value of the effectiv polarisation coefficient α for the atom chain obtained if

$$4\ 52\, \alpha \geqq a^3 \qquad (2)$$

The sign > corresponding to a negative value of α need not be distinguished from the sign = in both cases the atom chain is characterised by th instability of the electron chain connected with it This instability which has been noticed previously by Hertzfeld was interpreted by him as an indication of the fact that the electrons no longer remain bound but become free conduction electrons Thus the inequality (2) was considered as characteristic of the metallic state in general I believe that it is characteristic not of the metallic state but of th supraconductive state a supraconductor being rather a dielectric with freely movable electron chains (that is with ε = ∞) than a metal

According to a theory of the metallic state developed in a rather qualitative way by Slater[2] and recently greatly improved and generalised by Schubin[3] the normal conductivity of a metal is due to a *partial ionisation* of the atoms a certain fraction s of all the atoms becoming positive ions and an equal portion (to which the corresponding electrons are attached) negative ions If these electrons are bound very weakly they may be considered as free in the usual sense of the word The conductivity of a metal is equal to the sum of the conductivities du to these free electrons or negative ions on one hand and the positive ions or holes on the other The mechanism of electrical conduction consists in the *individual* jumping of an electron from a negative ion to one of the neutral atoms surrounding it (which is thus converted into a negative ion) or from a neutral atom to a positive ion which thus becomes a neutral atom its rôle being switched over to th donor We meet with the same type of electric conduction in electronic semi conductors[4] The chief distinction between a metal and a semi conductor consists in the fact that in the former case $s > 0$ at the absolute zero of temperature (T) whereas in the latter case $s = 0$ at $T = 0$ increasing according to the Boltzmann equation ($s = ce^{-W/kT}$ where W is the ionisation energy) with the temperature

The elements which are likely to become supraconductors form an intermediary group in the sense that at ordinary temperatures they are relatively poor conductors like the ordinary semi-conductors the dependence of their conductivity on the temperature is however of the same character as that of typical metals (negative temperature coefficient) This means that in the case of these intermediary elements or half metals we have to do with substances which are characterised by a practically constant value of the ionisation fraction s Their small conductivity can be explained either by a small value of s or by a small mobility of the individual electrons (which seems the more probable alternative in view of the correlation between supraconductivity and the Hall effect discovered by Kikoin and Lasareff) The fact that, in ordinary circumstances, that is above the 'transition temperature' T_s these substances are not supraconductive can be explained by the finite value of their dielectric constant as determined by the polarisability of ions stripped of the conduction electrons The nature of the transition which takes place when the temperature T is decreased below T_c can thus be very simply interpreted by assuming that at this temperature s suddenly falls from a certain rather high value to *zero* and that the polarisation coefficient α of the resulting *normal* atoms with their full complement of bound electrons satisfies the inequality (2)* The very fact that the substance loses its conductivity (σ falling to zero along with s) thus transforms it from a metal into a dielectric with $\varepsilon \to \infty$ that is it becomes a supraconductor

Both the necessity and the sharpness of the transition $s \to 0$ (that is $\sigma \to 0$ and $\varepsilon \to \infty$) can be easily understood if we assume that the state $s = 0$ has a smaller energy than the state $s > 0$ It results from Slater s and especially from Schubin s calculations that the *lowest* energy level for polar (ionic) states *may* correspond to a *finite* value of s whether this lowest level lies below or above the energy level corresponding to $s = 0$ It can further easily be seen that the distance between the successive levels in a band of levels corresponding to a given value of s is very small compared with kT even for extremely low temperatures (of the order of a few degrees K) If further the *total* width of the band was also small compared with kT the entropy of the state $s > 0$ could be calculated as $k \lg g$ where g is the statistical weight of the whole band that is the number of ways in which the state s is realised Taking all possible distributions of the ns electrons (negative ions) and ns positive holes (positive ions) between the n atoms we get

$$g = \left[\frac{n}{(ns)\,(n - ns)}\right]^2$$

The transition $0 \to s$ is thus connected with an *increase* of entropy

$$\Delta\eta = 2k[n \lg n - ns \lg ns - (n - ns) \lg (n - ns)] \quad (3)$$

In reality the width of a band is of the order of 1 volt and therefore at least a thousand times larger than kT at the transition point This will result in a much smaller entropy increase $\Delta\eta$.

So long however as $\Delta\eta > 0$ it follows that the state $s = 0$ must be stable at low temperatures and the state $s > 0$ at higher ones

The transition temperature T_c as determined by the equality of the free energies of the two states is given by

$$T_c = \frac{\Delta\varepsilon}{\Delta\eta} \quad (\Delta\varepsilon = \varepsilon_s - \varepsilon_0) \quad (4)$$

Taking $s = \frac{1}{2}$ (which is probably an exaggeration) and calculating $\Delta\eta$ with the help of (3) we get $\Delta\eta = 1 \cdot 7k_B$ If $T = 4°$ (say) the transition energy $\Delta\varepsilon$ should be of the order of 14 small calories per gram atom This value is greatly reduced if the width of the energy band under consideration is large compared with nT its effective weight being accordingly small compared with g

We thus see that the second condition for supraconductivity is expressed by the inequality $\varepsilon_s > \varepsilon_0$ at $T = 0$ But this is not all Equation (1) is a good approximation so long as the chain like displacement of the electrons x is small compared with the interatomic distance a When x approaches $\frac{1}{2}a$ the electrons are pushed back by a force which varies more rapidly than the first power of x and can be overcome through the quantum mechanism of the tunnel effect If a large number of electrons N are moving together in a chain like way they behave like a particle with an N fold mass the transition probability being correspondingly reduced Now in his second theory of supraconductivity Kronig[5] has shown that a chain or as he puts it a linear lattice of electrons bound to each other in a quasi elastic way can be displaced through a periodic field of force (with a period a equal to the average spacing between the electrons) under the condition

$$h/b\sqrt{m} > a^2, \quad (5)$$

where h is Planck s constant m the mass of an electron and b is the rigidity coefficient of the electron lattice Putting $b = \tau e/a^3$[5] where τ is a numerical coefficient of the order 1 Kronig finds that the condition (5) is fulfilled if a is of the order of less than a few Ångström units This seems to show that a linear lattice that is chain of electrons is practically *always movable* with respect to the corresponding chain of atoms provided the condition (2) which is much more restrictive is fulfilled also In fact the latter condition seems to be the mathematical formulation of the possibility of treating the (bound) electrons as a kind of lattice I do not believe in the reality of the three dimensional lattices postulated by Kronig in his first paper He has himself shown that such lattices even if they exist could not be moved through the ionic lattice As a matter of fact one dimensional lattices or rather movable *chains* of bound electrons fully suffice for the explanation of supraconductivity Such chains need not be movable in all directions It is sufficient to assume that they should be movable in one particular crystallographic direction corresponding to the smallest spacing between the atoms the dielectric constant being infinite for this direction and preserving a finite value for all the others

In spite of its shortcomings Kronig s theory is certainly the nearest approach to the correct explanation of supraconductivity published hitherto, the present theory differing from it more in form than in essence The theory I advanced before which was based on the supposed stabilisation of the free electrons (against heat motion) by their *electromagnetic* action was wholly erroneous in this particular respect It was correct however in describing the motion of the electrons in the supraconductive state as an organised collective motion This led to the result that a metal must possess when in this state an enormous diamagnetic susceptibility This corollary subsists in the new theory and is corroborated by the fact recently discovered by Meissner that the magnetic permeability μ of a metal in the supraconducting state drops to zero A supraconductor can thus be described as a body with $\mu = 0$ and $\varepsilon = \infty$ its electrical conductivity σ in the exact sense of the word being either finite or even zero

A more complete account of the present theory will be published elsewhere

J FRENKEL

---

* This inequality is probably satisfied for all metals, although not all of them are supraconductors because for true metals s remains finite (and practically constant) down to the absolute zero of temperature while for supraconductors it jumps to a finite value slightly above it.

Flora of Tibet

THE plant collection made by Capt F Kingdon Ward in Tibet last year for the British Museum (Natural History) comprises about 750 items, and more than 5,000 specimens Some 500 species are included The bulk of the collection was made north of Rima (lat 28° 25 N, long 97° 0 E), in Zayul, south of the great snow range, and in Nagong north of the snow range The Nagong plants come from around Shugden Gompa (lat 29° 25 N, long 97° 0′ E)

The great range of snow mountains comparable to the Himalaya, and running approximately north west to south east, divides this part of Tibet into two South of this range, in Zayul the mountains are well wooded with deciduous and evergreen forest Oaks maples, birch, hornbeam magnolias, *Ilex* and *Rhododendron* species abound Higher up there is conifer forest North of the range in Nagong there is no forest and almost the only tree, found in a few favoured localities is *Picea lichiangensis* There is a number of shrubs especially species of *Lonicera Berberis Spiraea, Rosa Clematis* and *Cotoneaster* but chiefly the mountains are covered with a great variety of herbaceous plants Thus the snow range acts as a rain screen Amongst the most prominent alpine genera are *Gentiana, Primula Dracocephalum, Cremanthodium, Anemone* and *Androsace*

One of the principal results of the expedition was the definite recognition and delimitation of three floral zones in Tibet (1) the desert zone with very few species of flowering plants, (2) the outer plateau with a considerable alpine and a small woody flora, and (3) the river gorge country, divided into (*a*) upper gorge country with a large alpine flora and a few shrubs and trees (*b*) lower gorge country with a wealth of forest The discovery that the snow range is an eastern extension of the Himalayan range is also important from a phyto geographical point of view, as is also the observation that the glaciers on this range formerly extended a long way south Kingdon Ward has now been able to trace the southern limit of the ice during the last glacial epoch, from the eastern Himalaya right across to China, this advance of the ice had a profound influence on the flora

In Nagong where the snow line stands at about 19,000 ft, flowering plants in some variety were found above 18,000 ft, mostly, however, collections were made at 14,000–16 000 ft In Nayul, the snow line is lower most of the plants found in the Rima district were collected between 5 000 ft and 10,000 ft, a few alpines at 10,000–15,000 ft These last include several species of *Nomocharis*

One other type of flora requires mention—that of the deep Salween gorge, which was reached in August The heat was great the lack of water was conspicuous A peculiar flora of dwarf spiny or prickly shrubs occurs here (altitude 9,000–11,000 ft)

The southern country traversed is composed almost entirely of igneous rocks: the northern country almost entirely of sedimentary rocks, including limestones red sandstone and slate

On the return journey, the Mishmi Hills were crossed by a new route This country, being technically a part of Assam, falls within the Indian Empire, and few plants were collected there

In all, a number of new and little known plants were found, and the distribution of others, especially as between the Himalaya and Chinese mountains extended, though the most important results were the recognition of the several floral areas in Tibet and the proof of the Himalayan extension, with all that it implies in the distribution of plants in south east Asia Seed of about 180 species was secured also a number of photographs of plants in their natural surroundings

The regions which lie to the west of Shugden Gompa, between the Salween and the Tsangpo, still remain to be explored, before we can get an adequate idea of the flora of the river gorge country

Locust Control*

THE outbreak of locusts which began in the Sudan, Algeria and western Asia in 1926 and reached Kenya two years later, increased in intensity so greatly that it exceeded the powers of local checks and expanded rapidly into an enormous, widespread plague, ranging from Bechuanaland into Persia India and Turkestan It is estimated that the damage thus caused between 1927 and 1931 exceeds £6 000 000

The Government realised the significance and at once formed an organisation, which now appears in the form of the Locust Control Committee of the Economic Advisory Council, with headquarters at the Imperial Institute of Entomology, under the direction of Mr B P Uvarov

The work quickly became international Italy suggested a congress in Rome where war was declared upon the locust by an alliance of British Italian and French Governments, which have since been joined by the Belgian, Portuguese and Egyptian A striking illustration of the world wide interest in this war is seen in the list of works published during the period in question, which covers no less than 35 pages of the reports and includes papers in such unexpected languages as Chinese, Yiddish and Uzbeg, while there are 166 papers in Russian

The three species concerned are the desert locust *Schistocerca gregaria*, Forsk no doubt the same that plagued Pharaoh, the tropical form of the migratory locust, *Locusta migratoria*, L subsp, *migratorioides* R and F, and finally the red locust, *Nomadacris septemfasciata*, Serv The first is confined to the arid belt, and the great forests appear to offer a barrier even to flying swarms The migratory locust frequents the three types of savannah country, but is stopped by the deserts Its movements are due to reflexes dependent in temperate regions upon temperature, in hot countries upon humidity The life history of the migratory locust in the tropics is different from its cycle in the temperate zone, as the egg stage there is short but the adult long, so it is with the latter that the battle must be joined Spraying with poison dust from aeroplanes, particularly of the auto giro type, will probably be the solution, coupled with intelligence work in the home breeding areas, which are being investigated by four British, three French and several Indian entomologists

With the expansion of agriculture in Africa, the potential damage by locusts becomes vast indeed, but much valuable work has been done, and now that the organisation is in full swing, the outlook is encouraging M. B

Science News a Century Ago

Royal Geographical Society

"At the Anniversary Meeting, held on May 12, 1834, Mr W. R Hamilton, V P, in the chair, General the Right Hon Sir George Murray was re elected President, and Mr R I Murchison was elected a Vice President A report related that the Society had published, during the last year, the third volume of its *Journal*, in two parts, and a Map of America by Col Monteith; that the late African and Palestine Associations had dissolved themselves and transferred their funds to the Society, that the Royal Premiums for 1832 and 1833 were assigned to Capt John Biscoe and Capt Ross, and that the Council had subscribed 50l to a projected expedition into the interior of Africa from Delagoa Bay, and to another into the interior of South America—50l towards outfit, and 50l a year for three years It also noticed the formation of a branch society at Bombay Lieut Allen, the companion of the late Richard Lander, was present and exhibited a variety of his African sketches. A portrait of Lander, painted by Mr Brockedon, shortly before his departure, was presented by that gentleman to the Society. The Society have published the first part of Vol IV of their *Journal*" (*Gentleman's Magazine*, June 1834)

The first to receive the Royal Premium of fifty guineas (1832) was Richard Lander, for exploring the course of the Niger to the sea, next (1833), John Biscoe, for his circumnavigation of the antarctic continent and the discovery of Enderby Land and Graham Land Biscoe's voyage was chronicled only in the Society's *Journal*

The Padorama

The *Times* of May 12, 1834, describes an exhibition then on view at the Bazaar, Baker Street, London 'It consists of a continuous view of the railway and the adjacent country through which the line of road passes between Manchester and Liverpool The whole picture covers a surface of 10,000 sq ft of canvas and it is made to move on drums by mechanical power There is also a foreground detached from the principal painting which foreground is also moveable Along the railroad a great variety of waggons, carts, etc, attached to steam engines, are at intervals made to pass along This part of the exhibition was well contrived, the mechanism of the steam engines is accurately represented, and the pigmy passengers by whom the carriages are crowded might easily, so well is the deception of the whole effort preserved, be mistaken for living people of the full size of life"

Coins and Coining

On May 13, 1834, Mr William Wyon (1795–1857), the chief engraver at the Mint, delivered a lecture before the Society of Arts on 'Coins and Medals" in which he gave a sketch of ancient and modern coins, the progress of the art of coining and of modern medals After referring to the coins of the Greeks and Romans, and to the introduction of the various British coins, he said that one of the most important events in the history of the Mint in London was the introduction of the mill and screw Previous to the reign of Charles II, money was made by hammering slips of gold and silver to the proper thickness, then cutting the slips into squares, which were afterwards rounded and adjusted to the weight required After this, the blanks were placed between dies and struck with a hammer The mill and screw, or coining press, was invented in France, it is supposed by Antoine Brucher in 1553, and was first used in Great Britain during the Commonwealth At the Mint in 1834, there were eight presses, each press producing sixty pieces a minute In 1817 the daily production of coins was 343,000, while from January 4, 1817 until December 31, 1833 the sum coined in sovereigns and half sovereigns was £52,187,265 sterling One of the problems at the Mint was the selection of the best steel Fine steel as used by engravers was unfit for the purpose and coarse steel acquired fissures under the die press Even the best steel could be spoilt for want of skill on the part of the smith Casualties to dies were frequent but sometimes a pair of dies would strike three or four hundred thousand pieces The lecture was reported in full in the *Athenæum* of May 1834

Sir Charles Bell on the Brain

On May 15, 1834, Sir Charles Bell read a paper before the Royal Society on the functions of some parts of the brain and on the connexion between the nerves of motion and sensibility In the course of his paper he suggested that the best mode of inquiry into the functions of the brain and nervous system would be to trace the filaments of the nerves through the filamentary and striated substance of the brain and stated that the result of such an examination would show that two columns of motal and sensory nerves descend from each hemisphere of the brain and meet and decussate in the medulla oblongata He also entered upon a minute account of the medulla and of the various septa of nerves with which it is connected tracing the filaments upwards into the brain and downwards into the spinal column In concluding he remarked that the use of the cerebellum had not yet been determined with any tolerable degree of accuracy Bell at the time was surgeon to the Middlesex Hospital He had been admitted F R S in 1826 and in 1829 awarded a Royal medal for his discoveries relating to the nervous system

Death of H W Brandes

Prof H W Brandes who died at Leipzig on May 17 1834 was the first meteorologist to construct a series of daily pressure charts In his Beiträge zur Witterungskunde published at Leipzig in 1820 he discussed the weather over Europe of each day of 1783 He drew charts of equal deviation of pressure from normal and of wind direction these charts were not published and have been lost but a specimen chart was reconstructed by Hildebrandsson from Brandes material Brandes believed that the winds converged towards regions of rarefied air or low pressure In a later publication he discussed two cyclonic storms and demonstrated that they advanced from west to east across the earth s surface

In the year 1834 there was published the Narrative of a Voyage in the Southern Atlantic Ocean in H M Sloop Chanticleer in which W H B Webster gave what was probably the first printed account of the differences of average annual pressure between different parts of the world and attributed to these hitherto unrecognised differences the perpetual interchange and motions of the atmosphere

Belgrave Literary and Scientific Institution

Following the establishment of this institution at 30 Sloane Street the *Athenæum* reported in its issue of May 17 1834 the delivery of an opening lecture by Prof Robert E Grant whose subject was On the Nature Growth and History of Corals We read that there was a crowded and highly respectable audience and that the lecture was illustrated by a variety of beautiful specimens and diagrams also that the results of personal researches and ingenious experiments were detailed

Prof Grant who is referred to above was born in Edinburgh and was a graduate of the University there In his student days he was the frequent companion of Charles Darwin in excursions and walks Darwin (then) thought that he was dry and formal (Life) Grant contributed many papers to the *Edinburgh Philosophical Journal* and the *Memoirs of the Wernerian Society* In 1828 he took up duties in London as professor of comparative anatomy and zoology at University College and during forty six academic years never omitted a single lecture Appointed in 1837 he was for three years Fullerian professor of physiology at the Royal Institution By will Grant bequeathed his property collections and library to University College (*Roy Soc Proc* 23)

Societies and Academies

LONDON

Royal Society, May 3 W D WRIGHT The measurement and analysis of colour adaptation phenomena There is a main process of adaptation that operates through the regeneration of a photosensitive substance at a constant rate The instantaneous response aroused by a stimulus is directly proportional to the magnitude of the latter but owing to the process of adaptation the response is rapidly reduced to an approximately constant level This is the true interpretation of the constancy of the Fechner fraction as opposed to the suggestion that the response is proportional to the logarithm of the stimulus By locating the three hypothetical stimuli in the colour triangle corresponding to those sensations that can be modified in intensity but not in colour no matter what the colour of the adaptation may be it has been possible to determine the fundamental response or excitation curves R J LUDFORD Factors influencing the growth of normal and malignant cells in fluid culture media Significant differences have been found in the behaviour of different strains of tumours in mouse and rat serum Some tumours have not been grown as sheets of malignant cells in either mouse or rat serum other tumours have given good sheet growths in mouse serum but not in rat serum while still others have grown in both sera It is suggested that whether or not cells form sheets from explants in a fluid medium depends upon the adhesion of the cells to glass in that particular medium rather than upon growth promoting or growth inhibiting properties of the medium The presence of large numbers of active cells of the macrophage type interferes with sheet formation by malignant cells in fluid media This is regarded as due partly to crowding out of the malignant cell on the surface of the cover glass and partly to the phagocytic activities of the polyblasts It may be the activity of cells of this type accumulated around a tumour graft in an immune animal which prevents its growth

DUBLIN

Royal Dublin Society, February 27 J J NOLAN Observations of atmospheric electricity at Glencree The results for diurnal variation of ion content and rate of ion production in the lower atmosphere at Washington (Wait and Torreson) Canberra (Hogg) and Boston (Yaglou) were compared with those found at Glencree It is shown that there is considerable support for the view that the maximum in the rate of ion production occurs approximately simultaneously at these stations

Milk Production and the Farmer

IN an interesting speech delivered at the Taranaki Agricultural Society s Show on March 8 Lord Bledisloe Governor General of New Zealand discussed the questions of the proposed dairy products quota to Great Britain and the removal of the embargo on the importation of pedigree live stock from Great Britain Lord Bledisloe pointed out that while the British farmer must insist that the dairy industry should be made a paying proposition there is at the present time on the British market much imported foreign third grade dairy produce which is causing the slump in prices It was agreed at Ottawa that subject to the salvation from ruin of her own dairy farmers Great Britain would not stand by and allow New Zealand farmers to suffer permanent impoverishment either in dairy farming or in any other branch of husbandry The future of the Dominion depends upon its successful and progressive methods of pastoral husbandry and while the standard of quality in New Zealand produce is already very high it is being still further improved by scientific methods

The case for the removal of the embargo on the importation of live stock from Great Britain rests on the necessity for the introduction of fresh blood in those breeds of cattle and pigs in which the numbers in New Zealand are low and inbreeding prevalent At present the cost is prohibitive through unnecessary detention in some other country *en route* the risk of infection is small because of the short incubation period of foot and mouth disease and the long journey to New Zealand High quality in her produce is the first essential to success and New Zealand can afford no longer not to import pedigree animals direct from Britain and thus improve her live stock as her rivals are doing

The question of the proposed dairy products quota and the apparently conflicting interests of New Zealand and British dairy farmers which at the present time appear to threaten the existence of either one or the other have an important bearing on present day questions of milk production in Great Britain Both countries are ideally situated climatically for dairy production Up to the present time the British farmer has looked to liquid milk consumption as the outlet for his supplies, while the New Zealand farmer, being a long way from the market, has produced mainly butter for export Beef prices being so bad recently large numbers of British farmers have changed over from beef to milk production and now there is a large amount of milk which is surplus to the present requirements for liquid consumption

The question arises whether a quota should be put on New Zealand butter and the surplus British milk used for butter making In our opinion this would be wrong Under British conditions of high costs of production butter making on a large scale is not a paying proposition If the price of butter is raised by quota restrictions to the level at which it will pay British farmers to produce it then we shall see a return to the consumption of margarine by the poorer classes of the community From a nutritional point of view this is undesirable

What then can be done with the surplus milk now being produced in Britain ? In addition to immediate action with regard to beef prices—something perhaps rather more drastic and simple than the Fat Stock Commission s recent report visualises—a large portion if not the entire present surplus could be consumed as fresh liquid milk and thin cream (16–20 per cent fat) if our public could be persuaded to consume as much milk *per capita* as does the average American

No milk publicity campaign however will persuade the British public to consume more dairy products unless it shows them how this can be done There is a limit to the amount of milk which one can take as milk puddings But the thin cream market is virtually untapped The only choice open to the housewife between whole milk and the type of cream that almost defies extraction from its carton is the cream that rises to the top of the milk bottle or some tinned substitute Few people accustomed to thin cream in tea and coffee and as an accompaniment to puddings porridge fruit and breakfast cereals would give it up unless forced to do so A demand for this commodity stimulated among the middle and upper classes would suit the farming community very well for it would leave skim milk on the farms for pig feeding—a supplementary protein feed which is badly needed to assist quality of the carcase of pigs sold under the Bacon Pig Marketing Scheme Danish bacon produced without skim milk would lose its characteristics

The large American consumption of milk however is mainly brought about by the city office workers consuming milk with their light lunch whereas the British take tea or coffee It is by serving milk attractively in bottles off ice that the American has been persuaded to drink it Tepid milk as it is too often served in Great Britain is not a clean drink and does not quench the thirst as iced milk does like cocoa tepid milk leaves a thick taste in the mouth so in the absence of iced milk the British public prefer a clean drink like tea or coffee for lunch Stimulation of the consumption of the surplus milk in Great Britain in these ways—iced milk and thin cream—would not only be more profitable to the British farmer and avoid doing injury to the business of the New Zealand farmer but would also be to the nutritional advantage of all classes of the British community

Leadership in Local Government*

THE very attention which the growing complexity of the problems confronting the administrator whether in national or industrial life has attracted makes it easy to overlook the extent to which technical factors have become important in local government also In the last twenty years the powers and duties of local authorities have greatly increased They have now far reaching responsibilities and the welfare of the community is largely dependent on the efficiency with which those responsibilities are discharged Public health education housing town and country planning road construction and maintenance—these are only some of the activities of local government authorities and more and more they require to have at their disposal officers on whom they can rely fully both for advice on the critical questions which come before them and for the execution of their decisions when taken

The local government service in Great Britain maintains a high standard for which no small share of the credit is due to the National Association of Local Government Officers This and other associations have laboured to secure improved qualifications of their members and have succeeded in developing an invaluable professional spirit and outlook In spite of this there are wide variations in the standards of recruiting and training of officers for local government service No consistent efforts are made by local authorities as a whole to secure the best persons for their service and to make the best use of them Recruitment is often haphazard and training is unsystematic Although technical qualifications where held are usually fairly high not all the qualifications are entirely satisfactory, and thorough investigation of the field is required

---

* Ministry of Health Report to the Minister of Health by the Departmental Committee on Qualifications Recruitment Training and Promotion of Local Government Officers Pp 91 (London H M. Stationery Office 1934) 1s 6d net

Investigation of the technical qualifications of local government officers was excluded from the scope of the recent inquiry into the qualifications, recruitment, training and promotion of such officers carried out by a Departmental Committee of the Ministry of Health under the chairmanship of Sir Henry Hadow, but the report none the less discusses a number of important factors bearing on the training of administrators competent to deal with the many important technical issues involved in local government service While the Committee recognises the importance of appropriate technical and professional qualifications in the principal departmental officers, it points out that the functions of any chief officer of a major department are mainly administrative, and it is of opinion that, in the past, local authorities have not laid sufficient stress on the administrative qualifications

The essential problem in local government to day is to ensure that the service offers an attractive career for vigorous minds and strong personalities Methods of recruitment, training, grading, promotion and remuneration are of importance as they contribute to this primary purpose The satisfaction of this end indeed offers the only adequate safeguard against incompetence or corruption in the public service, and is accordingly an essential factor in the redemption of the politician from his low position in public esteem and in the restoration of confidence in democratic institutions

Among the factors which promote the supply of administrators of the requisite quality, recruitment on a wider basis is essential, and for this reason the Committee insists not merely that local authorities should draw their professional and technical officers from all available sources, whether within the service or without, but also that difficulties in the way of recruiting university graduates without technical qualifications must be overcome No source of supply of the rare and invaluable quality of leadership can safely be neglected, but it is equally important to remember that administrative powers can be developed by training and experience The recommendations that deliberate efforts should be made to arrange to give promising young officers practical experience in administration and to encourage the study of the principles of public administration are vital

The report is happily free from the suggestion that technical and scientific officers as a class are lacking in administrative ability It is recognised that individuals of high professional or technical standing may be lacking in this quality, it is therefore the more important to recognise it and develop it where found The report outlines principles which are fully as valid in industry or in the Civil Service as in local government service, whereby the requisite combination of technical knowledge, professional integrity and administrative capacity may be encouraged and brought to bear on the complex problems of to day Its recommendations for centralisation and unification of the service, like those bearing on promotion and remuneration, are significant so far as they contribute to the main purpose of creating a service which compares sufficiently well with those obtaining in private enterprise to secure a proportion of the ablest minds and strongest characters of each generation

Chemical Factors in Plant Growth

Croissance des végétaux Par Dr Albert Demolon (*Principes d'agronomie*, Tome 2) Pp ix+307 (Paris Libr Dunod, 1934)

DR DEMOLON is well known as one of the clearest thinkers and one of the most ingenious minded among agricultural investigators As chief scientific advisor to the French Ministry of Agriculture he is kept in close touch with the practical problems of the French farmer, and as head of the research laboratories at Versailles he is equally closely associated with modern movements in science In his earlier publication, "La Dynamique du Sol", he dealt with the formation and composition of soils and the changes occurring therein, in the present volume, which is by way of a continuation, he discusses the relations between the soil and the growing plant, the subject which as he truly points out is the foundation on which rests scientific agriculture

In the first section of the book the author discusses the physical factors determining plant growth the effects of light, of temperature, electricity and of various rays also the amplitude of variations in yield due to meteorological conditions

The greater part of the book deals with the chemical factors concerned in plant growth the atmosphere, nitrogen and the mineral elements. The author sets out the facts clearly and discusses them with considerable penetration He has the happy power, common to the best French writers, of choosing the words that best express his ideas, and of saying what he has to say clearly, tersely and accurately

A useful summary is given of the part played by mineral elements other than the nitrogen, phosphorus and potassium which for long were the only substances considered to have fertiliser value The standard fertilisers for many years past have in point of fact supplied other elements superphosphate contains about 50 per cent of gypsum , the usual potassic fertilisers contain sodium or magnesium or both basic slag contains iron manganese and other elements In ordinary practice therefore, farmers have been adding compounds of calcium, magnesium, sodium iron, manganese, sulphur and chlorine along with the nitrogen potassium and phosphate But with recent improvements in technical chemistry, it is no longer necessary to use crude salts as fertiliser, and some of the new concentrated fertilisers attain a degree of purity hitherto unapproachable in agricultural practice The question is now beginning to interest agricultural experts whether they should advise farmers to add deliberately to their soils some of the substances they have been adding only incidentally It seems certain that in absence of these various elements, plant growth becomes abnormal and certain so called physiological diseases are likely to be induced This subject has been studied at the Institut Pasteur, Paris, at Rothamsted, the Waite Institute, Adelaide, various United States experiment stations and elsewhere The author deals at some length with magnesium, which is now attracting some interest in France Additions of manganese and boron to the soil seem to be necessary in certain cases, otherwise definite disease symptoms appear, but Dr Demolon is less certain about the need for adding some of the other elements which refined water cultures show to be necessary

Another subject now attracting much attention among agriculturists and discussed at length by the author, is the possibility of toxin formation in soils Some substances, hydrogen sulphide for example, are readily formed in anaerobic conditions others, such as excess of soluble salts, may be brought in from outside, for example, by sea floods Plant roots were at one time supposed capable of excreting substances toxic to themselves if not to others, then the idea was dismissed , but Pickering's work at Woburn shows that there may be something in the old idea, and H G Thornton at Rothamsted has shown that lucerne seedlings certainly excrete something that stimulates bacterial development in the soil and that might therefore have some effect on other plants The author summarises the facts clearly and concludes that no definite pronouncement can yet be made on this difficult subject

After an interesting and succinct account of the relations of soil micro organisms and plant growth, the author proceeds to summarise the present position in regard to the quantitative expression of plant growth phenomena by curves and equations He discusses in the first instance the qualitative changes, the seedling stage rapid vegetative growth, and maturation , these are not separated in point of time and at no time is the plant simply adding to its substance The simpler formulæ put forward to express the relation between the supply of nutrients and the extent of growth are none of them satisfactory though some of them may be sufficiently approximate to serve as a rough guide in fertiliser practice Here too the author adopts a cautious reserve and prefers to await the result of further experiment before making too definite a pronouncement

We can cordially recommend the volume to the student, both on account of its matter and of its presentation E J RUSSELL

Celestial Mechanics

Planetary Theory By Prof Ernest W Brown and Prof Clarence A Shook Pp xii+302 (Cambridge At the University Press, 1933) 15*s* net

THERE are various definite theorems bearing on the impossibility of solving the problem of three (or *n*) attracting bodies What is certain in a practical sense is that no general solution is attainable in a form suitable for comparison with observations even for a limited interval of time

Special methods have been devised for the two distinct types of motion which are present in the solar system, the motion of the planet and the motion of the satellite In the latter case, when the satellite is identified with the moon, there results a problem of quite special character and quite extraordinary complexity At the same time, it is essentially a single problem not lending itself naturally to piecemeal treatment Adams, it is true, succeeded in discussing some of its leading features in an elementary way, besides obtaining some original results of value in theory and method G W Hill again laid the foundations of a new theory without pursuing the subject beyond the preliminary stage But in general the lunar theory is a theme for the specialist prepared to make it his life s work Such a devotee was found in Prof E W Brown who has had the satisfaction of seeing his vast undertaking completed in every detail Now with a collaborator he has brought his experience gained in the more special field to bear on the wider and more varied problem of planetary motion

The design of the present work is very different from that of the treatise on the lunar theory for which a generation of students has been indebted to Prof Brown There he reduced to an orderly scheme all the methods of proved value in the development of the subject Here the ultimate object is the production of a general theory as required for comparison with observation in the various cases which arise Practical methods marked by an underlying unity are developed with this aim in view No attention is given to the history of the methods or to such theoretical aspects of the subject as those with which Poincaré concerned himself These can be found elsewhere There is an austere suggestion about this book that traffic ought to be confined to the public highway and that stragglers along the bypaths ought not to be encouraged The authors have certainly done much to consolidate the main road and even the inveterate rambler will appreciate their good work

Elementary chapters provide a sufficient introduction for the reader who has no previous acquaintance with the subject In a later chapter the direct calculation of the co-ordinates in terms of the true orbital longitude as independent variable is treated by an advantageous modification of a method given by Hansen Apart from this the work is based mainly on the use and transformation of elliptic elements There is a very valuable section on the disturbing function and its derivatives developed by various methods The use of canonical equations with the allied transformation theory is very clearly explained Thus it is shown that the terms of short period can be separated and removed by a single process and in the case of disturbing planets with periods unrelated to that of the body considered the problem of the motion presents comparatively little further difficulty

The first approach to more difficult conditions was found in the case of the long inequality of Jupiter and Saturn arising from the nearly commensurate periods of the two planets But problems of a completely different order are offered by the minor planets when the periods stand in a simple ratio to that of Jupiter within limits which amount to resonance Criteria for these limits are investigated with particular detail for the ratio 1/2

The Trojan group of asteroids have the same period as Jupiter and to these the final chapter is devoted The peculiar feature of their orbits is a long period libration in longitude It becomes necessary to introduce non integral powers of the mass of the controlling planet and the disturbing action of Saturn is so modified by the presence of Jupiter that separation of the effects is impossible and the problem becomes necessarily one of four bodies This feature has been familiar in the planetary perturbations of the moon it is a new circumstance in planetary theory The discussion of resonance and the treatment of the Trojan group of planets constitute the most original parts of the present work and will be found most interesting as well as valuable

Remarks on the limitations to be attached to certain familiar results relating to the stability of the planetary system will be found at several points and they are no doubt just But it is a little hard to see the mean distance dethroned from its place as a linear parameter of special character Naturally it owes this position in spite of its name not to any mean or average property but to its occurrence in the simple statement of Kepler s third law That point however has not been overlooked (see p 67) or the necessity for strict definitions to which it is allied In the third equation on p 216 there is a slip (of little importance) not noticed in the errata

It should be added that this valuable work has been admirably produced at a price which must be considered extremely moderate

The March of Inorganic Chemistry

A Text-Book of Inorganic Chemistry for University Students By Prof J R Partington Fourth edition Pp viii+1062 (London Macmillan and Co Ltd 1933) 15s net

A GENERATION or so ago inorganic chemistry appeared to have frozen into immobility and life in this field of science was easy and pleasant for both the author of an inorganic chemical textbook and his readers How different is the position to-day, when both writer and student can enter so whole heartedly into the feelings of the Gilbertian policeman ! So we find that in the twelve years succeeding its first publication, Prof Partington's treatise has had to undergo no fewer than three extensive overhauls in order to keep its readers reasonably up to date The subject still remains fluid , for, as the author remarks in his new preface "Very recent investigation of the structure of atomic nuclei will probably before long considerably amplify and modify present views on atomic structure, and the student who wishes to ascertain the current state of this investigation must follow the periodical literature "

In the new edition, Prof Partington has taken every care to keep his readers abreast of modern theory and practice in pure and applied inorganic chemistry, and the book retains its position as one of the best available for regular use by university students, and for reference by advanced pupils in schools There is no need to add here to the wide spread encomiums which Prof Partington's work has deservedly received , but attention may be directed to some outstanding alterations in the new edition The chapter on atomic structure has been reorganised so as to include a revised account of Werner's co ordination theory , newly found isotopes of hydrogen and other elements have been noticed , a tabulated list of the electronic structures of the rare earth elements has been added, as have also certain electronic formulæ , the account of active nitrogen has been revised , and there is a general discussion of hydrides These are straws showing the way the wind blows in inorganic chemistry at the present time The wise restraint which has been exercised in keeping the work, in true scientific fashion, "at constant volume" (1062 pp) is to be commended JOHN READ

Short Reviews

Biology in Everyday Life By John R Baker and J B S Haldane Pp 123 (London George Allen and Unwin, Ltd , 1933) 3*s* 6*d* net

THIS little collection of essays consists of six slightly modified talks broadcast in the spring of last year Five of them are by Dr Baker, and their scope is well indicated by the titles— A Biologist's View of Everyday Life Social Life in Animals" "The Determination of Sex ' The Quality and Quantity of Mankind ' War, Disease and Death This series becomes, as it progresses, increasingly socio biological and Prof Haldane's concluding essay on Biology and Statesmanship ' forms a logical ending

It would be easy to raise doubts and queries about many things in this book especially about Dr Baker's views implicit or explicit, on human genetics and its social implications, but it would not be fair to do so without bearing in mind the very serious limitations felt by the scientific writer, or speaker, when he has to address a lay audience on a technical subject It is only the rarest of expository geniuses who is able to combine absolute simplicity with complete accuracy Dr Baker is a little too afflicted with Dr de Kruif's 'baby language' technique, and Prof Haldane is just a little too objective and didactic for one to feel that either of them has yet reached the highest summit in this very difficult branch of scientific literature

In any event the proof of such a book is in the reading Presumably the authors intended to stimulate an interest in biology generally, and especially in the bearings of biology on the thought and activity of the ordinary citizen Whether or not they have succeeded must be a matter of experiment Our experience was that the effect on a lay person of reading these essays was to stimulate a flow of highly pertinent questions, by no means all easy to answer Indeed, many of them could only be answered by reference to further and somewhat more detailed or advanced books Since this is presumably exactly the effect the authors wished to achieve, it points to the conclusion that their little volume is to be regarded as very successful A L B

Gleichgewichtsfiguren Rotierender Flussigkeiten Von Prof Leon Lichtenstein Pp viii+175 (Berlin Julius Springer, 1933) 15 60 gold marks

THIS book may be regarded as a pendant to the author's "Foundations of Hydromechanics" and extends the same rigorous methods to the treatment of the problem of the equilibrium of rotating masses of liquid under their own gravitational attractions It summarises researches carried out by the author and his pupils during the past six years, mainly on existence problems of figures of equilibrium, of rotating masses of liquid in the neighbourhood of known figures of equilibrium, of homogeneous and also of heterogeneous masses of such liquid An integro-differential equation is constructed in each case and solutions are sought by the method of successive approximations, both for classical problems, such as those of Laplace and Liapounoff, and for new ones concerning one or more coaxial rings, Roche's satellites, liquid double stars with and without solid centres

The work constitutes a very valuable contribution to the literature of the subject and presumes a knowledge of calculus, potential theory and integral equations, but it is by no means easy reading, even for those possessing this knowledge, owing to the abstract nature of the reasoning employed It is well printed and commendably free from misprints, and will prove indispensable to all proposing to make a study of this branch of hydrodynamics

Yuman Tribes of the Gila River By Leslie Spier (The University of Chicago Publications in Anthropology Ethnological Series) Pp xviii + 433 + 15 plates (Chicago University of Chicago Press , London Cambridge University Press, 1933) 19s net

THIS study of the Yuman tribes of the Gila River, Arizona, is based upon field work sponsored by Yale University and the University of Chicago It is concerned primarily with the Maricopa, although the community since the beginning of the nineteenth century has been composite, the reason being that it has been Maricopa in speech and organisation since its formation Little of ancient custom remains The old outlook persists best in everyday behaviour, mannerisms, personal relations and speech Few are Christians The sib system, and its attendant naming habits is the most flourishing part of the old thought system Dr Spier by his investigation makes a valuable addition to the excellent series of studies of the Indians of California and the adjacent south west, for which the University of California has made itself responsible

The Physician's Art an Attempt to Expand John Locke's "Fragment De Arte Medica' By A G Gibson Pp vi + 237 (Oxford Clarendon Press , London Oxford University Press, 1933) 7s 6d net

DR A G GIBSON modestly describes his book as an attempt to expand John Locke's fragment De Arte Medica"—the opening of what was to be an essay on the philosophy of medicine, but which was left uncompleted Locke's words may have inspired the task, but Dr Gibson's views on the fundamentals of medical art are in no way an expansion of Locke's ideas , they are the reflections based not only on a professional life rich in experience in the arts of diagnosis, prognosis and treatment, but also on a real understanding of medical ideals and ethics Few doctors can be so perfect in their art that they have no lesson to learn from this book, and to the practitioner with most of his experience before him it will be of greater value than a stock of textbooks and scientific articles

The Spread of Tumours in the Human Body By Dr Rupert A Willis (Monographs of the Baker Institute of Medical Research, No 2) Pp x + 540 + 48 plates (London J and A Churchill, 1934) 25s

To the clinician, the secondary tumour is of significance only in its prognostic finality , for the pathologist, the importance of the primary relegates the metastatic growth to the background Yet much may be learnt about malignant tumours from a study of their paths in spreading and the nature of the tissues in which they prefer to form secondary growths Extensive study of records, critical consideration of theories, and the most painstaking and minute post mortem examinations, are the essentials in such research work , by adherence to them, Dr Willis has well surveyed a neglected corner of the field of morbid processes His book, if of limited interest to the physician and surgeon, is of primary importance to the pathologist, and an essential addition to the cancer research worker's library

Geographical Regions of France By Prof Emmanuel de Martonne Translated from the latest edition by H C Brentnall Pp xi + 224 (London William Heinemann, Ltd , 1933) 7s 6d

PROF DE MARTONNE'S work, which has had more than one edition in the original French, does not cover the whole of France but most of the important areas find a place and no essential feature of the framework of French geography seems to be omitted The book is the outcome of a course of lectures first delivered in the United States, and aims at relating the physical facts with the human interests The outstanding physical features are clearly explained and the book succeeds in giving a rational explanation of the contrasts in scenery exhibited by different parts of France It can be recommended for lucidity of exposition and simplicity of treatment

Einführung in die theoretische Physik By Prof Dr Clemens Schaefer In 3 Bänden Band 3, Teil 1 *Elektrodynamik und Optik* Pp viii + 918 (Berlin und Leipzig Walter de Gruyter und Co , 1932) 37 50 gold marks

THIS book contains a very complete account of electricity and magnetism in all their theoretical aspects, from the simple electrostatic field through crystal optics to the theory of relativity The treatment is clear, but it is quite definitely designed to appeal to the mathematician rather than to the experimental physicist The standard attains that of a postgraduate course, but the book lacks bibliographical details which one normally expects to find in a work of such importance

Struktur der Materie Vier Vortrage Von Prof P Debye Pp iv + 50 (Leipzig S Hirzel, 1933) 3 gold marks

IN this little booklet of fifty pages, Debye publishes four stimulating talks on the scattering of X rays by molecules, the electrical structure of matter, the molecular structure of liquids—including a fascinating account of the Brillouin derivation of the ratio of the velocity of sound to the velocity of light—and on the nature of solutions of electrolytes

Modern Ideas on Nuclear Constitution

By Dr. G. Gamow

WHEN the complexity of atomic nuclei was proved by the existence of spontaneous and artificial nuclear transformations, a very important question arose. From which of the elementary particles are the different nuclei built up? It seemed that this question could be simply answered as there were only two particles with pretensions to be elementary: the proton and the electron. The protons had to account for the main part of the nuclear mass and the electrons had to be introduced to reduce the positive charge to the observed value. For example, the nucleus of bismuth, with atomic weight 209 and atomic number 83, was considered to be constructed from 209 protons and $209-83=126$ electrons. It was also accepted as very probable that these elementary particles build up inside the nucleus certain complex units constructed from four protons and two electrons each (α particles). All this construction was in good agreement with the experimental evidence as electrons, protons and α particles were really observed being emitted in nuclear transformations.

The theory treating the nuclei as constructed of α particles, some protons and a certain number of electrons was worked out by Gamow. Although this theory gave some interesting results as to the general shape of the mass defect curve and the conditions of emission of α particles, it met with serious difficulties. It was very difficult to understand on the basis of the quantum theory of the electron how the electron can exist in a space so small as that limited by the nuclear radius. It was also not clear why the nuclear electrons, behaving in quite a strange and obscure way, do not affect the processes of emission of the heavy nuclear particles, protons and α particles.

About two years ago, it was shown by Chadwick that the experimental evidence forces us to recognise the existence of a new kind of particle, the so called neutron, also with claims to be held to play an important rôle in nuclear structure. The discovery of neutrons considerably simplified the difficulties about electrons in nuclei. One could now suppose that the nuclei were completely constructed of neutrons and protons (for example the nucleus of bismuth from 83 protons and $209-83=126$ neutrons) which probably sometimes unite to form an α particle (two neutrons and two protons). Thus the first of the above mentioned difficulties was, so to say, hidden inside the neutron, while the second one was actually removed.

On the basis of these new ideas, Heisenberg succeeded in building up a general theory of nuclear structure, accounting for the main features of nuclear stability. The basis of his theory is certain assumptions about the forces acting between neutrons and protons. It seems most rational to accept the view that the interaction between particles of the same kind is only due to electric charges (that is, no forces between two neutrons and the usual Coulomb repulsion between two protons), while between two different particles (neutron and proton) strong exchange forces come into play. These last forces are probably of the same kind as the forces between atoms playing the main rôle in quantum chemistry, and may be considered as due to the exchange of charge between the two particles in question.

This hypothesis explains at once why the number of nuclear neutrons for heavy elements is considerably greater than the number of protons (that is why the ratio of atomic weight to atomic number increases for heavier elements). In fact, if we neglect the Coulomb forces, the most stable state of the nucleus will correspond to equal numbers of neutrons and protons, as in this case all the possibilities of binding (by attracting exchange forces) between protons and neutrons are saturated. The presence of the Coulomb repulsion between protons will, however, shift the optimum in the direction of a smaller number of protons and the position of lowest potential energy of our system will correspond to the larger proportion of neutrons. As the importance of the Coulomb forces increases with the nuclear charge, one can understand that an equal number of neutrons and protons is possible only for the lightest elements (first ten elements of the periodic system) while for heavier ones the number of neutrons predominates (126 neutrons and only 83 protons in bismuth).

Accepting the simplest form for the law of variation of the exchange forces with distance —

$$I = a\, e^{br} \qquad (1)$$

and applying the quantum statistical method, Heisenberg calculated the behaviour of the nuclear model constructed from n_1 neutrons and n_2 protons. The result is that the particles are rather uniformly distributed inside a certain volume proportional to the total number of particles. This result fits very well with evidence otherwise obtained, that the density inside the nucleus is rather uniform and does not depend greatly on the atomic weight. The formula obtained for the total binding energy E of the nucleus as a function of n_1 and n_2 looks rather complicated and depends, of course, on the numerical values of the coefficients a and b in the expression (1) for the exchange force. Comparing this formula with experimental values of the mass defects of different nuclei, one can estimate the values of a and b. One finds thus $a=4.05\times10^{-5}$ erg, $b=1.25\times10^{12}$ cm^{-1}.

Very interesting consequences can also be obtained from Heisenberg's theory concerning the question of nuclear stability. It is easily understood that nuclei with a high positive electric charge must tend to emit positive particles From the point of view of the energy balance, the most favourable case for such emission is the emission of an α particle, as this removes from the nucleus a large amount of negative energy (the binding energy of the α particle itself), which is equivalent to the supply of an equal quantity of positive energy The condition for the possibility of α emission can be simply formulated if we consider it as a simultaneous subtraction of two neutrons and two protons from the nucleus in question The work necessary for such subtraction is evidently

$$\frac{\delta E}{\delta n_1}\,\Delta n_1 + \frac{\delta E}{\delta n_2}\,\Delta n_2$$

or as

$$\Delta n_1 = \Delta n_2 = -2$$

$$-2\left(\frac{\delta E}{\delta n_1} + \frac{\delta E}{\delta n_2}\right)$$

To make a spontaneous α disintegration possible, this quantity must be smaller than the above mentioned energy supply due to the binding energy $\Delta M_\alpha c^2$ of the α particle from neutrons and protons (The difference appears as the kinetic energy of the emitted particle) Thus the condition for α decay will be

$$-2\left(\frac{\delta E}{\delta n_1} + \frac{\delta E}{\delta n_2}\right) < \Delta M_\alpha c^2 \qquad (2)$$

In Fig 1 the ratio of the number of neutrons to the number of protons is plotted against the number of protons for all known isotopes The α stability curve as calculated from formula (2) is represented by a broken line (curve I) and one can see that it is situated too low One notices how ever that the theoretical curve apart from absolute values gives a good idea of the general form of this stability limit We may notice that the condition for the spontaneous emission of a proton

$$-\frac{\delta E}{\delta n_2} < 0 \qquad (2')$$

will give us a stability limit located very far to the right of the α stability curve, which means that spontaneous proton decay could only take place for very heavily charged nuclei (atomic number >200) On the other hand, the condition for the emission of a neutron

$$-\frac{\delta E}{\delta n_1} < 0 \qquad (2'')$$

is never fulfilled, which can easily be understood if we remember that neutrons, having no charge, are not at all repelled by nuclei

We must now turn our attention to the question of the emission of light particles From the point of view of the neutron-proton model of the nucleus, we must accept the view that the process of ordinary β emission is due to the transformation of a nuclear neutron into a proton with the liberation of negative charge in the form of an electron

$$n \longrightarrow p + \overset{-}{e}$$

On the other hand, the recent discovery of the Joliots of elements emitting positive electrons suggests the possibility of the reverse process

$$p \longrightarrow n + \overset{+}{e}$$

We can easily estimate the stability limits for such processes if we consider the emission of a nuclear electron as the subtraction from the nucleus of a neutron and simultaneous addition of a proton The condition for the positive energy balance of such a transformation will evidently be

$$-\frac{\delta E}{\delta n_1} + \frac{\delta E}{\delta n_2} < \Delta M_n\, c^2, \qquad (3)$$

where ΔM_n is the mass defect of a neutron as constructed from a proton and an electron In an exactly analogous way we obtain for the possibility of emission of a positive electron the condition

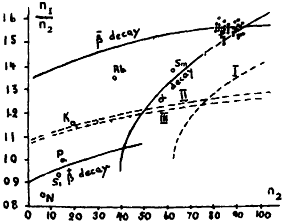

FIG 1 A map of all known nuclei Stable nuclei are indicated by full points unstable nuclei by small circles

$$-\frac{\delta E}{\delta n_2} + \frac{\delta E}{\delta n_1} < \Delta M_p\, c^2, \qquad (4)$$

where ΔM_p is the mass defect of a proton as constructed from a neutron and a positive electron From (3) and (4) we can conclude that the nucleus can be stable relative to electron emission only if

$$-\Delta M_p c^2 < -\frac{\delta E}{\delta n_1} + \frac{\delta E}{\delta n_2} < \Delta M_n c^2,$$

conditions which correspond in the stability diagram (Fig 1) to a very narrow band (curves II and III)*, in contradiction with the experimental evidence

The stability region can, however, be made much broader if we consider more closely the energy conditions connected with electronic emission from nuclei The point is that for a given total number of neutrons plus protons (that is, for given atomic weight) the nuclei are considerably more stable if the number of protons is even (even atomic number) The reason for this is that, with the increasing number of protons, each second one will lead to the formation of a new α particle, and consequently correspond to larger liberation of energy Thus if we plot the binding energy of isobaric nuclei against the atomic number (Fig 2) the points corresponding to even numbered elements will lie on a lower curve than those corresponding to the odd numbers As can be seen from the diagram, this will have the result that for a series of elements extending some way both to the left and to the right side of the minimum the emission of one electron (either negative or positive) will be energetically impossible In such cases only the simultaneous emission of two electrons can be considered but as can be estimated from general theoretical considerations such a double emission has extremely small probability The possibility is not excluded that the natural β activity of potassium and rubidium has its origin in such a double process which would easily explain their extremely long period of life

---

* From the equations $n = p + \overset{-}{e} + \Delta M_n c^2$ and $p = n + \overset{+}{e} + \Delta M_p c^2$ we obtain $\Delta M_n c^2 - (-\Delta M_p c^2) = \Delta M_n c^2 + \Delta M_p c^2 = \overset{-}{e} + \overset{+}{e} = 2mc^2 = 1{\cdot}6 \times 10^{-6}$ erg This corresponds in Fig. 1 to a breadth of the stable region of about 0·016 units along the ordinate.

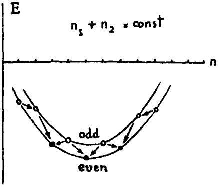

FIG 2 Mass defect curves for typical isobaric nuclei ● stable nuclei o unstable nuclei

According to these considerations we must push the limit of $\bar{\beta}$ stability upwards and the limit of $\overset{+}{\beta}$ stability downwards and thus get a considerably broader stability region It can be seen from Fig 1 that theoretical limiting curves give a good idea of the form of the actual stability limits, although just as in the case of α decay the curves go again too low It seems that both discrepancies have a common origin

In Fig 1 the points corresponding to unstable nuclei are shown by small circles One notices that in the region of the heavy elements, where α and β stability curves run rather close to one another (and possibly cross), the sequences of α-disintegrations followed by two β disintegrations are possible For the lighter elements only a few cases of spontaneous disintegration are at present known Samarium (most probably its lightest isotope) emits α particles of about 1 5 cm range and has an average life of about 10^{11} years The lightest isotopes of nitrogen silicon and phosphorus (N^{13}_{7}, S^{27}_{14}, P^{30}_{15}), unknown in Nature and produced artificially by the Joliots by α bombardment of boron, magnesium and aluminium, give $\overset{+}{\beta}$ particles with an energy of 1–2 million volts and possess life periods of several minutes

The $\bar{\beta}$ emission from potassium and rubidium must be explained either as a double electron emission from their heavier isotopes (K^{41}_{19} and Rb^{87}_{37}) or as due to some unknown isotopes of chlorine and bromine resulting from a very short range α emission of the above mentioned elements (probably from K^{41}_{19} and Rb^{87}_{37}) As these ranges in air as calculated theoretically from the value of the corresponding decay constants, are 0 24 cm and 0 63 cm respectively one can understand why the α particles have not yet been detected Thus we see that our general theoretical considerations fit rather nicely with the experimental evidence

We now turn our attention to the details of the processes of emission of α particles and electrons and the connexion of the disintegration energy with the average period of life The process of α emission can be explained on the basis of the ordinary wave equation of Schrodinger as the velocities of the emitted α particles are small compared with the velocity of the light It was shown by Gamow and independently by Gurney and Condon that the long life of α decaying bodies is due to the fact that the α particle leaving a nucleus must cross a very high potential barrier the transparency of which is extremely small and decreases very rapidly with the decrease of the energy liberated in the disintegration Theory leads us to the following formula for the decay constant λ as a function of the α particle velocity v

$$\lambda = \frac{4h}{mr_0^2} e^{-\frac{8\pi^2 e^2}{h}\frac{(Z-2)}{v} + \frac{16\pi e\sqrt{m}}{h}\sqrt{Z-2}\sqrt{r_0}} \quad (5)$$

where Z is the atomic number of the disintegrating element and r_0 the nuclear radius Accepting r_0 for radioactive elements to be of the order of magnitude $10^{\,13}$ cm one obtains very good agreement between the calculated and measured values of λ and can explain theoretically the empirical relation between lgλ and v found by Geiger and Nuttall

For complete agreement one must, however accept the view that the nuclear radius r_0 changes from one element to another in such way that the density of the nucleus remains constant ($r_0 \sim \sqrt[3]{A}$) Formula (5) permits us also to estimate one of the values λ or v if the other is measured Thus for example, the range of the α particles of radium C, estimated from this formula to be equal to 4 cm , is in good agreement with the value found later by Rutherford, and the period of life of the very short lived product radium C' given by this formula ($10^{\,6}$ sec) fits well with the recent measurements of Jacobsen

It is also interesting to notice that formula (5) may be successfully applied in the region of the lighter elements According to (5) the period of life of samarium as estimated from the velocity of its α particles must be about 10^{11} years in good agreement with the observed value

In the process of α decay, it may often happen that the nucleus of the product of disintegration is constructed in an excited state, which corresponds to the emission of α groups with slightly smaller energy (fine structure of α rays) The formula helps us to understand the relative intensities of such α groups and also permits us to draw certain important conclusions about the quantum numbers of the different excited nuclear levels On the other hand, it also explains the small number of so called long range α groups corresponding to the disintegration of excited nuclei

In contrast with the theory of α decay the understanding of the process of β disintegration presents serious difficulties First of all the electrons emitted in β decay possess a continuous distribution of energy, which seems to be in contradiction with the law of conservation of energy It was pointed out by Bohr that the law of conservation of energy need not necessarily hold for processes involving nuclear electrons for which the modern quantum theory is not applicable But, as was shown by Landau the rejection of the conservation law for energy will be connected with very serious difficulties in the general gravitational theory, according to which the mass present inside a certain closed surface is entirely defined by the gravitational field on this surface It was proposed by Pauli that one might retain the energy conservation law by the introduction of a new kind of particle called a 'neutrino These neutrinos, having no electric charge and possessing very small (or even vanishing) mass would be practically unobservable in all experiments and could easily take away the surplus energy of β-decay The existence of such particles is, however, at present rather doubtful

An attempt to construct a theory of β-disintegration on the basis of Dirac's relativistic wave equation, treating the emission of a nuclear electron in a similar way to the emission of light quanta by an atom, has recently been made by Fermi In this theory, one accepts the view that the transformation of a nuclear neutron into a proton is connected with the creation of an electron and a neutrino which, being born leave the nucleus, dividing between them the energy liberated in this transformation Accepting a definite value for the interaction energy giving rise to such transformations (of the order of magnitude of about 10^{14} erg) Fermi obtains reasonable values for the decay constants of β disintegrating elements and a good fit with the correlation curve between the decay constant and the maximum energy of the β particles as found by Sargent

An interesting consequence of this theory, which however, is much more general and will hold for every theory treating electron emission as the result of the transformation of a neutron into a proton, is a definite exclusion rule for β decay According to this rule β transformations in which the original nuclei and those produced possess different spins are not all permitted, and can only happen with a rather reduced probability (about a hundred times less often than transformations in which the spin does not change) This explains at once the two different curves obtained by Sargent as due to permitted and not permitted transformations It has been shown by Gamow that the application of the above mentioned exclusion rule for β decay to the analysis of radioactive families gives very good results and permits us to give definite spin values to normal and excited states of radioactive nuclei

MM Osty's Investigations of Rudi Schneider

(From a Correspondent)

SCIENTIFIC men who have been anxious to form a fair and impartial opinion about the alleged physical phenomena of spiritualism have found it very difficult to do so There exist, indeed, records by a number of qualified scientific observers which if taken at their face value would establish the reality of these phenomena completely We may instance the names of Crookes, Zollner, Richet, A R Wallace, Varley, De Morgan, Lodge, W J Crawford and R J Tillyard These records have not produced general conviction, even in the view of those who have adequately studied them before undertaking to express an opinion, though it appears that those who have studied them have often been considerably impressed The accounts given are often insufficiently detailed to satisfy the student The possibilities of deception, of conjuring, of malobservation, and even of hypnotic suggestion acting on the observer and causing him to see the thing that is not have been difficult to estimate It is not often that the good faith of the experimenter has been questioned Indeed, to profess a belief in these things has been so manifestly contrary to the personal interests of a scientific worker, that it would be gratuitous to suggest that his adhesion is inspired by anything but the love of what seems to him to be the truth The circumstance that a poor light has usually been insisted upon is extremely suspicious, and justifies a very reserved attitude It is proper to remark, however, that in some recorded instances the light has been good

The object of this article is not to present a general or historical review of the subject, but to give a short account of some of the observations of Dr Eugène and M Marcel Osty with Rudi

Schneider described in a work entitled *Les Pouvoirs Inconnus de l Esprit sur la Matière* published in 1932 (Paris Félix Alcan) These observations should be of special interest to physicists because they were in large measure carried out by self recording instruments The graphs are reproduced for the student to examine and he can form his own opinion of them Mal observation and hypnotic suggestion as possible explanations are therefore largely excluded The possibility of deliberate deceit remains and will require to be carefully assessed But the scope for it seems to be much restricted as compared with previous investigations

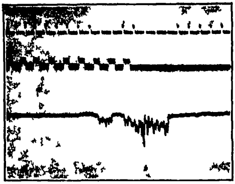

FIG 1 Top scale of seconds, advancing from left to right middle intermittent time signal bottom infra red intensities as ordinates and times as abscissæ

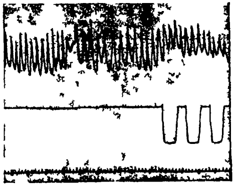

FIG 2 Bottom seconds and fifths advancing from right to left (note the change in middle signals synchronous with the other diagram top chest movements as ordinates and times as abscissæ

Attention was initially fixed on the alleged phenomenon of telekinesis or moving of objects by an unknown agency in the presence of the (controlled) medium It is generally known that a beam of light can be used to guard a treasure a warning bell being rung when a potential thief approaches it too near and intercepts the beam The method has been used when valuable objects are on public view It depends on an obvious application of a photoelectric cell combined with a thermionic valve actuating a relay Now it occurred to MM Osty that by using a beam of infra red light instead of visual light this method could be carried out in a dark séance room and that the object (flower handkerchief and the like) proposed for telekinesis could be guarded by the beam so that if the medium succeeded in escaping from the controller who was by way of holding him and attempted to seize the handkerchief in order to move it a bell would ring and give warning The controller would then be doubly on his guard and what was more important a flashlight photograph could be taken which would decisively reveal whether the medium or anyone else was doing anything suspicious It will probably be agreed on all hands that this was a well conceived plan of experiment not suggestive of undue credulity on the part of the experimenters

It was found that in fact the bell did ring on frequent occasions while the medium was or purported to be in trance The ringing was sometimes maintained for half a minute or even a minute Flashlight photographs were taken while the bell was ringing and they revealed the medium sitting in his usual hunched position with his head sunk forward his hands held and his knees between the knees of the controller Some of these photographs are reproduced in the volume one of the best is on p 45 There is nothing to be seen in the path of the infra red beam

It seems therefore that whatever it was that obstructed the beam it was not an ordinary solid obstacle Whatever obstruction it was that caused this effect seemed to fade away under the influence of ordinary light for lateral illumination of the path of the beam although it did not reveal anything had the effect of promptly stopping the ringing of the bell

Although the infra red beam was intercepted as if something was trying to reach the handkerchief or other object the latter was not often moved and the experimenters wisely decided to abandon this as a primary object of study and to concentrate attention on the unexplained phenomenon that was more easily obtained namely the obscuration of the infra red ray The bell was replaced by a galvanometer with a photographic recording drum adapted to give a continuous graph of the deflections The obscurations previously indicated by the bell were now photographed on the drum which gave a record of intensity and duration

After the work had been in progress for some time the ordinary galvanometer which had been in use was replaced by one of quick period (one tenth sec) with the view of examining in more detail how the obscuring action set in A very significant fact was then noticed When the ray was (partially) obscured it was seen that the galvanometer spot moved in sympathy with the loud and rapid breathing of the entranced medium The deflection was less (and the absorption therefore greater) during an inspiration *or* an expiration than at the times intermediate between the two It was clear therefore that the obscuring action was connected directly or indirectly with the medium's muscular processes This fact alone seems to rule out confederacy

When the above relations had been recognised, arrangements were made for automatically recording the motions of the medium's chest, at the same time as the infra red absorptions A scale of seconds was placed on each record, and by an obvious electrical method, synchronous signals were made on each so as to afford a time origin from which to measure the frequencies Sample records (Figs 1 and 2) are here reproduced from MM Osty s memoir The absorption lasts for 7 seconds, and oscillates with a frequency of 5 per second At the same time the breathing is at the rate of 2 5 per second These are the figures given by MM Osty They can be approximately verified from the half tone blocks in their publication, though the individual oscillations are not invariably well resolved in the reproduction

In attempting to estimate the work of MM Osty, we must consider in what directions there might be a chance of shaking their evidence Mere topics of prejudice should be avoided It has often been suggested that Rudi Schneider makes use of confederates, either secretly introduced, or openly present in the guise of sitters Will it help us to assume that he did so in this case ? The answer appears to be in the negative It is not apparent how a confederate could assist in producing the rhythmic obscuration in time with Rudi Schneider s breathing When it has been shown that an assistant, working without disguise can do this, the hypothesis of confederacy will require closer examination

Again it has often been argued that Rudi Schneider can get an arm free in spite of the apparent control This hypothesis has the same weakness as the previous one How can he use the (hypothetical) free arm to produce the effects ? No answer to these questions has so far been forthcoming

Lastly, is it possible that MM Osty were deceived, and that the records which they imagined they had obtained on their photographic drums were really prepared independently by Schneider or some confederate of his, and palmed off on MM Osty before development in substitution for their own records ? It must be remembered that the relation between Schneider's breathing and the infra red intensity was first noticed visually by the motion of the galvanometer spot, before it had been recorded photographically, so that this hypothesis also seems to fail

The value of the evidence of MM Osty, or of any other witnesses must depend on what view is taken of their good faith This in turn must depend on general reputation, on internal consistency and coherence of evidence, and on the possible motives for deception

It would be of the greatest importance for the work to be independently repeated in some other laboratory Unfortunately, Rudi Schneider's powers are apparently failing Some have considered this fact to be in itself suspicious It must be remembered however, that even at their best the phenomena were sporadic, with many blank sittings interspersed In any event, it is not clear why the trick, if trick it was, should not continue to be played as long as it is profitable On the alternative hypothesis it seems not particularly unlikely that exceptional natural powers of this kind might pass off with time, as do, for example, the powers of 'calculating boys'

Anyone who sees his way to a normal explanation for these effects would be doing a service to the cause of truth by setting up the apparatus and producing graphs similar to those published by MM Osty

---

Obituary

Prof A N Meldrum

By the death of Prof Andrew Norman Meldrum on March 12 the activities of one of the best informed writers on historical matters relating to eighteenth and nineteenth century chemistry have come to a close The history of the greater movements in the progress of theoretical chemistry formed a favourite branch of study and research, and from an early period Prof Meldrum's attention was directed to the subject of the atomic theory, in connexion with which he published, so early as 1904, a thoughtful and elaborate monograph on "Avogadro and Dalton The Standing in Chemistry of their Hypotheses" This was followed by a series of papers "On the Development of the Atomic Theory", contributed to the Literary and Philosophical Society of Manchester in 1909–11, and by a pamphlet with the same title published in India in 1920 He was engaged during a number of years upon an intensive study of the works of Lavoisier and his contemporaries In this period he accumulated a large amount of material for the production of the successive lengthy papers that appeared between 1924 and 1934, dealing with Lavoisier s part in The Eighteenth Century Revolution in Science', with his historic Three Notes on Combustion 1772' and with his 'Early Work in Science 1763–1771 Besides these valuable papers, Meldrum contributed one of the three special commemorative addresses on Joseph Priestley that were read before the Chemical Society in April 1933, on the occasion of the bicentenary of that philosopher

In his published historical work, Meldrum appears as a close student as well as a keen and, at times, outspoken critic He was not willing to accept, without verification, the statements made by compilers, but was in the habit of making it a point to obtain first hand information from original sources In the case of his researches into Lavoisier's work, this usage involved the making of extensive inquiries in Paris, not only by correspondence but also by personal visitation, and in this way he ensured the authenticity of his own statements. After the publication, so recently as last January, of his concluding Lavoisier paper, he had begun a study of the life and work of Black and was actively engaged a few days before his unexpected death in a minute examination of the contemporary and subsequent literature relating to Black's discoveries.

Meldrum studied chemistry with Japp at Aberdeen and took his D.Sc. degree at the University there in 1904, his graduation thesis being the Avogadro Dalton monograph already mentioned. Afterwards he carried on research work in organic and in physical chemistry in collaboration with Japp, Perkin, jun., and others. In 1912 he was appointed to the professorship of chemistry in the Madhavlal Ranchhodal Science Institute, Ahmedabad, from which he was transferred later to the Royal Institute of Science, Bombay, both of these institutions being affiliated to the University of Bombay. From his post in the latter he retired in 1931 and resided thereafter in Edinburgh. He is survived by his widow and two daughters.

MR. R. LL. JONES LLEWELLYN

MR. RICHARD LLEWELLYN JONES LLEWELLYN, who died suddenly on April 19, had made a lifelong study of rheumatism and allied disorders, on which he was regarded as an eminent authority. The son of Surgeon Major Morris Jones of Aberystwyth, he assumed the name of Llewellyn in 1911 on his marriage to the Hon. Mrs. Crosse of Hulbertson, only child of the fourth Lord Headley.

Llewellyn had been president of the Balneological and Climatological Section of the Royal Society of Medicine, consulting physician to the National Hospital for Rheumatism at Bath, member of the conference on chronic arthritis convened by the Medical Research Council, chairman of the Medical Committee of the National Campaign for the Prevention and Relief of Heart Disease in Children, and vice president of the British Committee on Rheumatism, International Society of Medical Hydrology. He was also a member of the Board of Medicine, Welsh National School of Medicine, a fellow of the Royal Society of Medicine, of the Hunterian Society and of the Royal Meteorological Society.

In his researches into rheumatic diseases, Llewellyn was greatly helped by his brother, A. Bassett Jones.

Llewellyn was the author of several books and articles on rheumatism, arthritis, fibrositis and gout. At the time of his death he was engaged on a study of the relations of rheumatism to the absence of sunshine and the consequent failure of the skin to mobilise the chemical antecedents of the endocrines, a new view which has attracted considerable attention in the United States.

Llewellyn had been a member of the central appeals tribunal of the Ministry of Pensions, and was widely quoted as the author of "Malingering or the Simulation of Disease" (1917) and "Pensions and the Principles of their Evaluation" (1919). Llewellyn's style was picturesque and vivid; his conversation was arresting, original and spiced by shrewdness and humour.

MR. C. E. BORCHGREVINK

CARSTEN EGEBERG BORCHGREVINK, whose death at Oslo is announced, was born in that town, then Kristiania, in 1864. After an education in Norway and Saxony, he went to Australia in 1888 and spent some years in Queensland and New South Wales, first as a land surveyor and later as a teacher of modern languages and natural science.

When in 1894 Svend Foyn sent a ship to the Antarctic under the command of L. Kristensen and H. J. Bull to explore whaling possibilities, Borchgrevink signed on as an ordinary seaman, having failed to get accepted as a passenger. The ship reached lat. 74° S. in the Ross Sea and Borchgrevink in landing at Cape Adare was one of the first to set foot on the Antarctic continent. He also was the discoverer of plant life within the Antarctic Circle.

Returning to Europe, Borchgrevink tried in vain to equip a trading expedition to South Victoria Land to search for guano. In 1898, however, he induced Sir George Newnes to fit out the *Southern Cross* (formerly the Norwegian whaler *Pollux*) for a scientific expedition to the Ross Sea, the first since that of Sir James C. Ross in 1841. A wintering was made at Cape Adare where many valuable observations were made by L. Bernacchi, N. Hanson and others, and on the return of the ship in spring a voyage was made south to the Barrier face. Borchgrevink and W. Colbeck travelled over the Barrier to lat. 78° 50′ S., at that time a southern record.

In 1902 Borchgrevink investigated volcanic conditions in the West Indies on behalf of the National Geographic Society and in the later years of his life was curator of the Tömte Biological Station in Norway. He received the Patron's medal of the Royal Geographical Society in 1930, and a medal of the Royal Scottish Geographical Society in 1900. His chief publications were "First on the Antarctic Continent" (1901), "Das Festland am Sudpol" (1905) and "The Game of Norway" (1920–25). R. N. R. B.

WE regret to announce the following deaths:

Dr. Angel Gallardo, formerly Argentine Minister for Foreign Affairs, rector of the University of Buenos Aires since 1932, and president of the Academy of Sciences in Buenos Aires since 1927, aged sixty-six years.

Prof. C. W. Rolfe, emeritus professor of geology in the University of Illinois, an authority on the geology of Illinois, on April 6, aged eighty-three years.

News and Views

Prof A Fowler, F.R S

PROF A FOWLER, who, at the meeting of the Royal Astronomical Society on May 11, was presented by Dr Edwin Hubble with the Bruce Medal of the Astronomical Society of the Pacific, is the *doyen* of English speaking spectroscopists So long ago as 1885, he became attached to the Solar Physics Observatory at the Royal College of Science under the late Sir Norman Lockyer, with whom he remained until 1901 when, on Lockyer's retirement, he was given the charge of the astrophysical work of the College The intimate experience he acquired of the practical aspects of spectroscopy—a subject much more specialised then than now—was turned to good account, and his share with Lockyer in recognising the existence and importance of 'enhanced' lines (the basis of modern ionisation theory) was rapidly followed by the attribution of the *M* type stellar absorption bands to TiO and the 'comet tail' bands to low pressure CO, the identification of many solar spectrum lines with bands of water vapour and magnesium hydride, and other astronomical work of the first importance

THE sudden prominence given to spectroscopy in 1913 by Bohr s theory of the hydrogen atom offered an opportunity for the application of Prof Fowler's peculiar knowledge which he was not slow to accept The interpretation of enhanced lines as radiations from ionised atoms in the general case was mainly due to his work, and in a series of subsequent papers he provided some of the most fundamental observational data for the extraordinary development of atomic physics in recent times Under his influence and direction, a considerable school of spectroscopists has grown up, and many vital contributions to modern spectroscopy have been made by workers who received their original impetus from him Prof Fowler was in large measure responsible for the organisation of the International Astronomical Union, of which he was the first general secretary, holding office for six years Since 1923 he has been Yarrow research professor of the Royal Society—a position from which he retires at the end of the present session In addition to the Bruce Medal, his long list of honours is to be augmented this year by the award of the honorary Sc D and D Sc degrees of the Universities of Cambridge and Durham, respectively

Sir Richard Redmayne, K C B

AT the annual meeting of the Institution of Civil Engineers held on May 8, Sir Richard Redmayne was elected president in succession to Brigadier General Sir Henry Maybury This is, we believe, the first time a mining engineer has been chosen for this position of distinction, and Sir Richard's election is a mark of recognition of his important services to Great Britain and to the mining industry generally Born at Gateshead upon Tyne on July 22, 1865, Sir Richard, after being taught privately, passed through the Durham College of Science, Newcastle upon Tyne, and at eighteen years of age began practical work in the Hetton Collieries, Durham, of which he became the under manager In 1891–93 he was in South Africa, and then returning home, was for eight years resident manager of the Seaton Delaval Collieries, Northumberland In 1902, at the age of thirty seven years, he was appointed professor of mining in the University of Birmingham, and to him fell the task of planning the Department of Mining Six years later he was appointed H M Chief Inspector of Mines, and this important position he held throughout the War and until 1920 He had previously been employed by the Government on official inquiries and he afterwards served on many committees and Royal Commissions appointed to inquire into the use of electricity in mines the organisation of rescue work, safety lamps, explosions and spontaneous combustion, and the organisation of the coal industry Both when at Birmingham and since his retirement from the Home Office, he has practised as a consulting mining engineer He has served as president of the Institution of Mining and Metallurgy and is a vice president of the British Science Guild and president of both the Institution of Professional Civil Servants and the Association of Scientific Workers

New Foreign Members of the Linnean Society

PROF CAMILLE SAUVAGEAU of Bordeaux, and Prof G Otto Rosenberg, professor of botany in the University of Stockholm, were elected foreign members of the Linnean Society at the meeting on May 10 to fill the vacancies caused by the deaths of Prof K von Goebel and Dr Erwin Baur Prof Sauvageau first came into prominence in 1877 by his work on Tunisian cryptogams in collaboration with N Patouillard Since then he has been concerned almost exclusively with the study of the brown seaweeds He has worked out the life histories of a number of these algæ, choosing representatives of all the natural orders, and was the discoverer of the filamentous gametophyte in Laminariales He has also made elaborate taxonomic studies of the difficult genera *Fucus* and *Cystoseira* based on extended collecting experience Sets of his specimens illustrating the monographs have been distributed to the principal herbaria Prof Rosenberg is well known for his cytological studies, mainly devoted to development in flowering plants His thesis for his doctorate in 1897 was on the physiological cytology of *Drosera rotundifolia* This was followed ten years later by an account of the cytology of the hybrid *Drosera longifolia* × *rotundifolia*, in which he established the occurrence of chromosome segregation Other valuable researches have been on the embryology and pollen development of *Zostera* and the discovery of the phenomenon of apogamy in *Hieracium* and *Crepis* His broad outlook on cytology has enabled him to make several generalisations which have had considerable influence on problems of taxonomy and phylogeny

Mr R H Burne F R S

THE retirement of Mr R H Burne from the physiological curatorship of the Royal College of Surgeons Museum was marked by a complimentary dinner which was held in his honour at the Langham Hotel on May 10 Among those present were Sir Holburt Waring Sir Cuthbert Wallace Sir Arthur Keith Sir Arthur Smith Woodward Sir Peter Chalmers Mitchell Dr Tate Regan Sir Charles Ballance Prof E Barclay Smith Prof William Wright Sir Buckston Browne Prof E S Goodrich and Mr C Forster Cooper Mr Burne s contributions to zoological and anatomical literature have been outstanding in that they have been the result of painstaking dissection of the most intricate kind The physiological series of the Royal College of Surgeons contains innumerable examples of his masterful skill with the scalpel Many of these preparations illustrate discoveries which he has himself made but has never published His election to the fellowship of the Royal Society in 1927 was the recognition of his scientific work in the College Museum The complimentary dinner was in its turn a mark of appreciation by his friends of his modest and retiring personality

Television Committee

THE Postmaster General announced in the House of Commons on May 14 that the Television Committee is to be constituted as follows —Lord Selsdon (chairman) Sir John Cadman (vice chairman) Col A S Angwin Assistant Engineer in Chief G P O Mr Noel Ashbridge Chief Engineer B B C Mr O F Brown Department of Scientific and Industrial Research Vice Admiral Sir Charles Carpendale Controller B B C Mr F W Phillips Assistant Secretary G P O The secretary of the Committee is Mr J Varley Roberts Telegraph and Telephone Department G P O E C 1 and the terms of reference are To consider the development of television and to advise the Postmaster General on the relative merits of the several systems and on the conditions under which any public service of television should be provided

IT does not appear that any of the members of the Committee appointed by the Postmaster General have that practical knowledge of the scientific problems involved in television desirable for the consideration of the position and possible development of the subject It will be difficult therefore for the Committee to estimate with authority the value of the various systems which have been developed Even in regard to the commercial interests involved and the attempts made in other countries to popularise television the Committee will have mainly to depend upon the experience or knowledge of others Moreover since the relative merits of the systems of television to be examined may have to be decided on patent issues it is strange that no member of the Committee familiar with patent law and practice has been appointed It seems therefore that the Committee will have to base its report upon evidence given by the various television interests and we suggest that it would have been better if the Postmaster General had convened a conference of these interests and asked them to present an agreed report on the two main questions submitted to the Committee he has appointed He might thus have had the fullest technical information on television presented to him direct by the companies who command the services of all the television experts available As it is the Committee will have a difficult task in securing such information and assessing its value and whatever report is issued is likely to be challenged by companies concerned with the development of television

Plague of Blood sucking Flies in Yugoslavia

WE learn from the *Times* of May 12 that an insect plague is causing serious trouble in parts of Yugoslavia The insect in question is referred to as the golubatz fly which has recently appeared in parts of the country not previously troubled by the pest Several peasants and some 500 cattle and sheep have already perished A poisonous fluid injected by the fly has the effect of breaking down the red blood corpuscles so that when the bites become numerous death may supervene From the account given it is evident that the fly in question is a species of *Simulium* or buffalo gnat This genus comprises blood sucking flies which are troublesome pests in several parts of the world In regions bordering on the Danube the species *S columbaczense* which is most probably the fly involved in the present outbreak causes at times heavy mortality especially among horses as the result of its blood sucking propensities Its larvæ and pupæ live in streams and rivers while the adult flies sometimes occur in immense swarms In 1923 an invasion in Rumania is computed to have caused a loss to farmers of about £80 000 through the deaths of horses sheep pigs and other domestic animals Although human beings are also attacked and severely bitten fatal cases seem to occur but seldom In their efforts to control the plague the farmers used smoke screens and applied various repellent smears to their stock Much the same methods are being used in the present outbreak the peasants lighting bonfires in order to protect their stock the herds being kept indoors during the day and allowed to graze only between sunset and sunrise A feature of such outbreaks is that the flies may be carried long distances by the wind with the consequent invasion of areas where the farmers have no previous experience in applying control measures

Dust Clouds in the United States

A RARE meteorological phenomenon was experienced in New York on May 11 when a cloud of grey dust enveloped that city This cloud of dust is described as having reached the eastern seaboard of the United States early on that day and is said to have extended from New England down to Washington to have been denser in the Middle West and to have measured 1 500 miles by 900 miles in the horizontal and about three miles in the vertical

The damage and discomfort caused by the dust was evidently very great A synoptic weather chart for that day prepared in the Meteorological Office Air Ministry from wireless weather bulletins supports the suggestion made in the *Times* that the dust was carried by the wind from a region in Western Canada and the neighbouring States which is suffering from severe drought for a vigorous circulation of wind around a deep cyclonic depression is shown on the chart and this circulation is in about the expected position Aeroplanes are said to have encountered the dust cloud the pilots having estimated that it was travelling eastwards at speeds between 60 miles and 100 miles an hour The phenomenon can safely be compared in its origin with the dust storms of Egypt and Northern India a fall of red rain in London due to a circulation of wind round an anticyclone which brought down dust from the Sahara —investigated many years ago by Shaw and Lempfert —was essentially similar in character It appears to be one of the attendant evils of North American droughts that fine tilth can be removed from its proper place in the farmers fields and be deposited in distant States where its presence —even in agricultural country—is far from being immediately beneficial

Centenary of Liverpool Medical School

ON May 11 the University of Liverpool celebrated the centenary of the Liverpool Medical School In connexion with the celebrations a brief illustrated account of the School by Arthur A Gemmell has been issued (The Liverpool Medical School, 1834 1934 Hodder and Stoughton, Ltd London 1*s*) On the occasion of the conferment of honorary degrees to celebrate the foundation of the School an address was delivered by Prof John Hay professor of medicine in the University Until 1821 St Bartholomew s St Thomas s Guy s and the London Hospitals held the monopoly of medical teaching then the barrier against provincial teaching was broken down by the Society of Apothecaries in recognising the teaching of Dr Joseph Jordan in Manchester In 1824 the clinical teaching at the Manchester Infirmary School was recognised thus Manchester was the first provincial medical school in England Undoubtedly the efforts of the Manchester medical men were a stimulus to those in Liverpool Anatomy schools were developed first and finally a School of Medicine In 1837 the School was recognised by the London Society of Apothecaries the College of Surgeons and the University of London In 1884 it was incorporated with University College when the latter which was founded in 1881 was admitted into Victoria University In 1903 when the University of Liverpool was granted its charter the School became its Faculty of Medicine Among the distinguished occupants of the endowed chairs in the past have been Lodge, Campbell Brown Herdman, Gotch, Paterson, Boyce, Sherrington Benjamin Moore and Ronald Ross

ASSOCIATED with the School of Medicine at Liverpool is the School of Tropical Medicine, with seats on the Faculty of Medicine This School was founded in 1899 and has the distinction of being the first of its kind in the world In 1921 the School established a permanent laboratory at Freetown Sierra Leone and already has a brilliant record of studies in malaria yellow fever sleeping sickness blackwater fever vomiting fever as well as entomology helminthology and tropical sanitation At the celebrations the honorary degree of D Sc was conferred on Prof H R Dean professor of pathology in the University of Cambridge Sir Thomas Lewis physician University College Hospital Mrs May Mellanby investigator for the Medical Research Council Wilfred Trotter Sergeant Surgeon to the King and LL D on Prof William Blair Bell emeritus professor of obstetrics and gynaecology in the University Prof H Briggs emeritus professor of obstetrics and gynaecology in the University Herbert R Hurter Liverpool past president of the Liverpool Medical Institution W S Paget Tomlinson lately chairman of the Public Health Committee of Westmorland Prof Charles H Reilly emeritus professor of architecture in the University of Liverpool

Excavations at Ur 1933 34

DR C L WOOLLEY s lecture on The Year s Work at Ur given at the Royal Institution on May 11 afforded his audience a more favourable opportunity of appraising the results of this brief season s excavations than has been possible from the summary reports which have appeared in the Press The elucidation and study of the earlier phases of the occupation of the site have been carried down through pre flood strata to the bottom of the marsh before man appears on the scene The history of the ziggurat dating in its present form from 2300 B C of the attendant temples of the First Dynasty (3000 B C) and of the antecedent buildings which they replaced has been brought back to the very beginning of the plano convex period while beneath have been found still earlier periods of which the later must belong to the Jemdet Nasr age It was not possible at this point in the excavation area to carry the work to its logical conclusion by deeper digging, but Dr Woolley traced the course of excavations at the south eastern end of the Temenos area from the modern ground level right down to virgin soil through deposits of the age of Nebuchadnezzar the Kassite age (1400–1000 B C) the Sargonid period (2600 B C) and through a continuation of the Royal Cemeteries of the fourth millennium It was at this point in what was evidently a soldiers burial ground that the unique discovery of a female statue deposited as a funerary offering was made Below this were the archaic written tablets and seal impressions and at a still greater depth the graves extending over a considerable period of time which have proved so amazingly rich in stone vases of varied form and material In the mixed soil in which as well as in the sandy flood deposit were found the earlier graves yielding Jemdet Nasr ware there were abundant sherds of Al Ubaid ware thus completing a remarkable record which covers the complete range of Mesopotamian history from the middle of the first millennium B.C. to man's earliest occupation of the site, a period of not less than three millennia, possibly more.

Parallels of Habits and Beliefs

THE Frazer Lecture was delivered at the University of Oxford on May 10 by Prof. H. J. Rose, of the University of St. Andrews. The title of the lecture was "Concerning Parallels", and Prof. Rose discussed the legitimacy of the sort of parallels to classical religious phenomena which Frazer uses, leading up to a discussion of polygenetic versus distributionist views in anthropology. His general argument was that the use of parallels between the habits and beliefs of one people and another, while particularly conspicuous in the works of Frazer, is nothing new, being prominent in works published so early as the eighteenth century. It has generally involved recognition of the principle laid down by Bergier (1760) that "partout les hommes se ressemblent". Frequently there has gone with it a shallow conception of human evolution, tacitly assuming that the resemblance between different peoples at approximately the same stage of culture is so close as to amount to identity, and also that the stages of culture can be dated by merely placing first in time those which appear simplest and most brutish. This being the result of false reasoning and the neglect of elementary philosophic principles, has led to unsound results. In consequence, the attempts of the so-called historical school, of which Graebner, Pinard de la Boullaye and W. Schmidt are outstanding representatives, to establish objective criteria of dating and a strictly scientific method of handling the facts must be welcomed, whether the results they have so far achieved are acceptable or not. The criteria are, however, open to serious objection. Examples can easily be found of usages from peoples, wholly unconnected ethnologically, illustrating each other in a most welcome fashion, the common humanity of the minds of both being more important than any specific difference. The most fruitful activity of an anthropologist is rather psychological than historical or geographical, although these aspects should not be neglected; and to misunderstand the motive of an action may result in failure to place it even in its right historical context.

Royal Cornwall Polytechnic Society

THE hundredth annual report of the Royal Cornwall Polytechnic Society is of unusual interest. It contains among other matter accounts of the hundredth annual meeting held at Falmouth on February 21, 1933, and of the centenary summer meeting held on July 18–21. At the opening session of the latter the president, Viscount Clifden, occupied the chair and a series of addresses of congratulation was presented on behalf of the Royal Society, Royal Institution and other bodies. During the four days there were excursions and visits to works, and five addresses were delivered by well-known men of science. Sir Richard Gregory's address dealt with "Science Applied to Industry"; Sir John Cadman spoke on "Science, One and All", making special reference to the operations in the oil fields of Persia and Iraq; Sir Napier Shaw on "Unofficial Meteorology"; Dr. G. C. Simpson on "Modern Methods of Weather Forecasting", and Prof. S. J. Truscott on "Problems of Mining at Great Depths". These addresses are printed in full in the report, and that by Sir Napier Shaw is accompanied by an interesting series of photographs.

FREQUENT references were made at the meeting to some of the pioneers in Cornish industry, and one of the visits was to the Safety Fuse Works of Messrs. Bickford Smith and Co., Ltd., Tuckingmill. The invention of the safety fuse was due to William Bickford, who had been struck by the frequency of accidents in mines and the number of men in Cornwall totally or partially blinded through them. Appended to the report is an account of the work of the Falmouth Observatory, which has actively co-operated with the Meteorological Office since 1868. This was referred to in the address of congratulation from the Meteorological Committee signed by Sir Philip Sassoon, Under-Secretary of State for Air. Recently the old observatory tower, where the observations were made from 1868 until 1885, has had a commemoration tablet fixed to it.

Photography of Sound

"SOME Photographic Aspects of Sound Recording" was the subject of the Sir Henry Trueman Wood Memorial Lecture, which was given by Dr. C. E. Kenneth Mees, of the Eastman Kodak Company, at the Royal Society of Arts on May 16. Dr. Mees stated that the introduction of sound recording has influenced every section of the motion picture industry, from the nature of the original material selected for the presentation to the architectural design of the motion picture theatre itself. Two methods of sound recording are in general use, leading in one case to records in which the density of the photographic deposit varies, and, in the other, to records in which the area occupied by the photographic deposit varies. Reproduction depends on three qualities, loudness, frequency of pitch and wave form quality or timbre. The intensity range is limited primarily by the ground noise, which is chiefly due to physical defects in the films, such as scratches and dirt, although even in a perfectly clean film there is a very small amount of ground noise due to the granular structure of the silver deposit. By the use of special apparatus it is now possible to reduce ground noise considerably. The reproduction of high frequencies is dependent upon the resolving power of the photographic film. Special experimental apparatus has been designed to analyse the wave form and quality of the reproduction. "Improvements in the reproduction of sound by photographic means," Dr. Mees concluded, "will depend, in the future as in the past, on intensive scientific research in relation to sound, electricity, and photography."

Historical Physical Apparatus

SIR HENRY LYONS, formerly director of the Science Museum, delivered his presidential address to the

Institute of Physics on May 15, taking as his subject Physics and Science Museums" Sir Henry referred in particular to the work which the Board of the Institute has done through a special committee in locating pieces of physical apparatus of special historical importance, and ensuring so far as possible that they should be preserved from deterioration or possible loss This committee was appointed in 1925, and since then it has brought to light many objects which were little known to physicists generally and of which the historical importance was not always appreciated at its full value It was not until the middle of the eighteenth century that the first institution was established for the preservation of scientific instruments and technical apparatus, this was the museum of the Conservatoire des Arts et Métiers in Paris, which was founded in 1794 to include all kinds of machinery, models, tools, instruments, etc Little can now remain of the instruments and apparatus in use in earlier times, not only because in those times there was no institution where they could be deposited, but also because for the most part their historical importance was seldom realised Then probably more than now, an instrument once acquired was treasured for there were few of them, but it passed in time to a later generation which neither appreciated it nor understood its importance The same influence operates to day and there is much difficulty in securing for posterity the more important examples of apparatus which has played a part in the advance of science The address will be published in due course and copies will be obtainable from the Institute of Physics, 1, Lowther Gardens, Exhibition Road, London, S.W 7 (1*s* 1*d* including postage)

A New Nature Reserve in New Zealand

THE property of Brooklands, New Plymouth, New Zealand, was handed over by the trustees of the late Mr Newton King to the Borough of New Plymouth as a public reserve and officially opened by His Excellency the Governor General, Lord Bledisloe, on March 10 It adjoins the beautiful Pukekura Park, and forms a natural extension of it Together they comprise an area of more than 100 acres, forming a park second to none in the Dominion either in size or natural beauty In addition to the actual property of Brooklands, the Trustees presented five acres of native bush nearby, and, to give access to it and make the whole one large reserve, Mr T C List and Mr C A Wilkinson gave an area of seven and a half acres In his speech, Lord Bledisloe, after paying tribute to the late Mr King, pointed out some of the many natural advantages which the Dominion possesses, and said that it is unique in the number, variety and grandeur of its many beauty spots within a relatively small area and in its incomparable native bush, he prophesied that eventually New Zealand will find its tourist traffic the main source of its wealth While admiring the fine specimens of introduced trees, Lord Bledisloe gave a word of warning against the mixing of exotic trees with the native vegetation All those who have the preservation of the native vegetation of the Empire at heart will feel grateful for the interest which Lord Bledisloe has in their efforts, and for the help he is giving them

Safety in X ray work

IN a paper to the Institution of Electrical Engineers read on February 22, by Mr L G H Sarsfield, safety measures for workers with X ray plant were discussed He discussed the risks of fatal injury and the advantages and disadvantages of using signal lights The concluding portion of the paper dealt with the use of high voltage flexible cable and described some new types of cable which are coming into use Stress was laid on the need for definite instructions so as to avoid electrical dangers He suggested that the Institution should co operate with the British Institute of Radiology in framing rules In the discussion, Dr V E Pullin said that at Woolwich they had to legislate for uninstructed use, and so had to make the equipment absolutely safe Dr G W C Kaye, speaking as secretary of the International Protection Committee which will meet at Zurich next July, pointed out that international recommendations were framed as the result of the British Protection Committee's work, and these recommendations play a very important part in the design of equipment all over the world The League of Nations has issued a very comprehensive publication on the subject The British recommendations are now being revised and he hopes that the use of rubber floor mats and insulating shoes will have more consideration Dr B J Leggett said that too much talk of the need of protection made patients nervous In some cases, too much protection will prevent results being obtained In reply, Mr Sarsfield said that there is a real need for earthing the conductor at intervals along its length

Rothamsted Experimental Station

THE appeal for funds to purchase the Rothamsted fields has now secured in cash or good promises the £10,000 necessary to claim the munificent donations of £15,000 by Mr Robert McDougall and £5,000 by the Sir Halley Stewart Trust (see NATURE 133 442, March 24, 1934) The success of the purchase scheme is therefore assured, and the appeal is being kept open only a few days longer in order to enable the Committee to obtain the further amount needed to meet the agreed addition to the purchase price consequent on the ascertainment of the tithe charges, timber evaluation and other items Several organisations still have to make their final decisions, but it is confidently expected that the whole amount including these additional payments will be secured within the next few days, so that the Rothamsted Committee can enter into possession free of all financial obligation and free therefore to devote the whole of its resources to the important agricultural investigations in hand.

Annual Meeting of the British Medical Association

THE one hundred and second annual meeting of the British Medical Association will be held in Bournemouth during the week commencing July 23 under the presidency of Dr S Watson Smith and an interesting account by Mr Bernard Calkin of some of the geological and archæological features in the neighbourhood of Bournemouth is given in the *British Medical Journal* of May 5 p 814 Palæolithic implements bronze and early iron age relics and Roman remains have been found in several localities Eight of the seventeen known Hampshire earthenware beakers of the Beaker Folk (*circa* 1700 B C) were found at Bournemouth Early Iron Age sites in Bournemouth generally yield little beyond pottery fragments whereas in similar sites around Swanage animal bones and bone implements are frequent being preserved in the limestone district there but perishing in the sand and gravel of Bournemouth

Announcements

PROF W J DAKIN Challis professor of zoology in the University of Sydney has been elected president of the Linnean Society of New South Wales

LIEUT COL S P JAMES of the Ministry of Health has been awarded the Darling Memorial Medal and Prize of the Health Committee of the League of Nations for his work on malaria therapy

THE Abbé Henri Breuil has accepted the presidency of the Prehistoric Society of East Anglia for 1934 and will give an address at the meeting of the Society at the rooms of the Society of Antiquaries Burlington House London on May 23 at 2 30 on Engraved and Sculptural Stone Monuments in the British Isles of the Transition Period between the Stone and Bronze Ages an Essay of Chronology and Interpretation Non members of the Society wishing to be present should apply to the honorary secretary Mr G Maynard The Museum Ipswich

THE following awards have been made by the Royal Aeronautical Society Simms Gold Medal to Sir Gilbert Walker for his paper on cloud formation Taylor Gold Medal to Mr A Plesman (managing director of K L M) for his paper on the Amsterdam Batavia service Wakefield Gold Medal to Señor J de la Cierva for his work on the development of the autogiro Busk Memorial Prize to Mr A V Stephens for his paper on recent research in spinning Pilcher Memorial Prize to Mr W H Lewis for his paper on duralumin in aircraft construction

THE Council of the Institution of Electrical Engineers has made the following awards of premiums for papers read during the session 1933–34 or accepted for publication Institution premium to W Kidd and J L Carr Ayrton premium to B A G Churcher A J King and H Davies Fahie premium to T S Skillman John Hopkinson premium to Dr W G Thompson Kelvin premium to B L Goodlet Paris premium to Dr J L Miller and J E L Robinson Webber premium to G Shearing Overseas premium to S P Chakravarti extra premiums to Dr M A B Brazier Capt B S Cohen C W Marshall P D Morgan W G Radley and Dr S Whitehead H Rissik *Wireless Section Premiums* Duddell premium to F Walmsley Extra premiums to L H Bedford and O S Puckle F B Moullin and H D M Ellis A H Reeves *Meter and Instrument Section Premiums* Silvanus Thompson premium to Dr A H M Arnold extra premiums to J B Lees Dr E Mallett G F Shotter *Willans Premium* for a paper dealing with the utilisation or transformation of energy Mr D B Hoseason for his paper on — The Cooling of Electrical Machines

PROF G ELLIOT SMITH writes Acting on the advice of my physicians I have been persuaded that it is essential on grounds of health to resign the position of president of the recently established International Institute of Psychical Research I deeply regret the necessity for this action at the present moment when the Institute is about to embark upon certain interesting experiments the results of which should afford ample justification for its existence

THE Royal Society of Edinburgh commemorated the completion of its hundred and fiftieth year at a meeting of the Society held on May 7 1934 with Sir E A Sharpey Schafer president in the chair Prof D Arcy W Thompson delivered an address entitled Fifty Years Ago In the evening the Lord Provost Magistrates and Council of the City of Edinburgh gave a civic reception to the fellows in the Galleries of the Royal Scottish Academy which as the Royal Institution was for more than eighty years the home of the Society

APPLICATIONS are invited for the following appointments on or before the dates mentioned —A University demonstrator in physical chemistry at the University of Cambridge Mr H Thirkill Clare College (May 24) A lecturer in biology at the Diocesan Training College Fishponds Bristol—The Principal (May 26) A chief assistant engineer to the Rivers Mersey and Irwell Catchment Board—The Clerk to the Board County Offices Preston (May 26) A psychologist at the North West District Child Guidance Clinic—The Secretary 18 Belsize Crescent London N W 3 (May 30) Junior technical assistants (mechanical engineers and chemists) in the Supply Board Technical Establishment under the Director of Ordnance Factories—The Under Secretary of State (C 5) The War Office London S W 1 (May 30) A lecturer in geology at the Wigan and District Mining and Technical College—The Principal (May 31) A head of the Civil and Mechanical Engineering Department and a lecturer in electrical engineering at the Northampton Polytechnic Institute St John Street London, E C 1—The Principal (May 31) A principal of the Municipal Technical College Bolton—The Director of Education Education Offices Nelson Square, Bolton (May 31) A lecturer in geography and a lecturer in mathematics at Lincoln Training College—The Principal An assistant lecturer in zoology and a lecturer in economics at the University College of North Wales Bangor—The Registrar (June 2)

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return nor to correspond with the writers of rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications]*

Radioactivity Induced by Neutron Bombardment

EXPERIMENTS have been carried out to ascertain whether neutron bombardment can produce an induced radioactivity giving rise to unstable products which disintegrate with emission of β particles Preliminary results have been communicated in a letter to *La Ricerca Scientifica* 5 282 1934

The source of neutrons is a sealed glass tube containing radium emanation and beryllium powder The amount of radium emanation available varied in the different experiments from 30 to 630 millicuries We are much indebted to Prof G C Trabacchi Laboratorio Fisico della Sanità Pubblica for putting at our disposal such strong sources

The elements or in some cases compounds containing them were used in the form of small cylinders After irradiation with the source for a period which varied from a few minutes to several hours they were put around a Geiger counter with walls of thin aluminium foil (about 0 2 mm thickness) and the number of impulses per minute was registered

So far we have obtained an effect with the following elements

Phosphorus—Strong effect Half period about 3 hours The disintegration electrons could be photographed in the Wilson chamber Chemical separation of the active product showed that the unstable element formed under the bombardment is probably silicon

Iron—Period about 2 hours As the result of chemical separation of the active product this is probably manganese

Silicon—Very strong effect Period about 3 minutes Electrons photographed in the Wilson chamber

Aluminium—Strong effect Period about 12 minutes Electrons photographed in the Wilson chamber

Chlorine—Gives an effect with a period much longer than that of any element investigated at present

Vanadium—Period about 5 minutes

Copper—Effect rather small Period about 6 minutes

Arsenic—Period about two days

Silver—Strong effect Period about 2 minutes

Tellurium Period about 1 hour

Iodine—Intense effect Period about 30 minutes

Chromium—Intense effect Period about 6 minutes Electrons photographed in the Wilson chamber

Barium—Small effect Period about 2 minutes

Fluorine—Period about 10 seconds

The following elements have also given indication of an effect sodium magnesium titanium zirconium zinc strontium antimony, selenium and bromine Some elements give indication of having two or more periods which may be partly due to several isotopic constituents and partly to successive radioactive transformations The experiments are being continued in order to verify these results and to extend the research to other elements

The nuclear reaction which causes these phenomena may be different in different cases The chemical separation effected in the cases of iron and phosphorus seems to indicate that at least in these two cases the neutron is absorbed and a proton emitted The unstable product by the emission of a β particle returns to the original element

The chemical separations have been carried out by Dr O D Agostino Dr L Amaldi and Dr L Segrè have collaborated in the physical research

Induced Radioactivity

CURIE and Joliot[1] and Ellis and Henderson[2] have observed that positrons were emitted when aluminium magnesium and boron were bombarded with high energy α particles They noted further that the positrons could be detected after the α particle bombardment had ceased It was therefore assumed that these electrons were produced by the radioactivity of the unstable nuclei resulting from the capture of the α particle and the expulsion of the neutron Danysz and Zwy[3] obtained similar results when they bombarded nitrogen with α particles

In order to account for the results obtained by bombarding certain ammonium salts in which hydrogen was in part replaced by diplogen with diplons Oliphant Harteck and Rutherford[4] assumed that a helium nucleus of mass 4 and charge 2 was formed by the union of two diplons which differed from the ordinary α particle in having a large excess energy and being in consequence unstable It is the purpose of this note to point out that in a similar manner the radioactivity of the light elements is due to the formation within their nuclei of an unstable proton of excess energy which disintegrates by emitting a positron It is suggested that the similarity of the disintegration phenomena observed is due to the radioactivity of this radioproton

It has been shown[5] that the emission of protons from neon magnesium silicon sulphur and argon can be explained by assuming that pairs of electrons are formed by the interaction of α particles and nuclei as suggested by a formula due to F Perrin[6] By assuming that the positron of the pair unites with a neutron to form a proton it was found possible to retain the hypothesis of stability of nuclei of mass 4*n* the feeble proton emission of the elements mentioned being due to the less abundant isotopes The mechanism was extended to the other proton-emitting elements and the conclusion arrived at in a previous paper[7] was confirmed namely that there are no free protons in nuclei these particles being combined with neutrons either as α particles or diplons This hypothesis will account for the induced radioactivity as follows

Consider for example the case of aluminium It is supposed that the proton emission is caused by the positron of the electron pair uniting with the free neutron the negative electron combining with the positron of the diplon to produce a quantum of γ radiation and leaving the stable nucleus $_{14}\mathrm{Si}^{30}$ When the energy of the α particle increases beyond a critical value it is supposed that the neutron is emitted before the high energy positron unites with it The radioproton is formed however as the positron unites with one of the two neutrons produced when the negative electron combines with the positron of the diplon This proton with excess energy disintegrates by emitting a positron From the reaction suggested it is expected that the positrons emitted will have definite energy and not a continuous range of energies as with the β rays of the normal radioactive elements The varying periods of disintegration are thought to be due to the varying nuclear fields in which the radioproton is formed

Further it is to be anticipated that similarly induced radioactivity will be observed with all elements which give rise to protons under α particle bombardment A full account of this hypothesis will be published shortly

Accurate Electron Diffraction Measurements

IN order to compare the diffraction pattern of a substance of unknown characteristics with that of a known material Shishancow and Tartarinowa[1] suggest using two convex specimens mounted face to face the two patterns being recorded simultaneously

This method is obviously inapplicable to transmission diffraction and in the case of diffraction at grazing incidence the defects compared with the double shutter method[2] will be apparent Thus (1) owing to the specimen shadows the two sets of rings do not meet at a common pattern boundary (2) the rings are not described about a common centre (3) structural changes of a single specimen cannot be recorded under comparative conditions and (4) since only two relatively small segments of the beam cylinder are diffracted rings corresponding to large Bragg plane spacings are obscured (1) (2) and (4) militate directly against the attainment of accuracy (3) precludes the application of the method to a wide range of interesting phenomena[3] and (4) is conducive to error in assigning the correct crystal structure

The hollow cylindrical type of beam employed by Shishancow and Tartarinowa and previously described by de Laszlo and Cosslett[4] is a phenomenon well known in high speed cathode ray oscillography and is often observed with a badly pitted cathode The effect can be still further exaggerated by the use of a discharge tube of a design unsuitable for the production of the homogeneous solid pencil of cathode rays employed by us in our experiments

Other workers[5] in this field besides ourselves have used curved surfaces wires, fibres etc Where possible however the flat or approximately flat surface is generally preferred partly on account of the ease with which it can be prepared and systematically explored with the beam and also because the ratio of diffracted to undiffracted electrons is higher

We have previously shown that the occurrence of any voltage change during the recording of a double shutter pattern is automatically rendered self evident in the resulting photograph[2] The double shutter method permits of the attainment of a high order of accuracy comparable with that of X rays and can be employed in both transmission and grazing incidence diffraction its successful practice however like that of precision spectrography, calls for suitable equipment and instrumental technique

Full Period Effect in Miller's Ether Drift Experiment

IN his memoir[1] on the ether drift experiment Dayton C Miller mentions that harmonic analysis of the curves of the displacements of the fringes obtained by a complete rotation of the interferometer puts in evidence in all cases the existence of a full period effect which accompanies the Michelson half period effect utilised in the elaboration of the results of the experiment The amplitude of the full period effect is of the same order of magnitude as the Michelson effect it is however proportional to the number of visible fringes in the field of view and—in the most favourable conditions for the experiment with six visible fringes—perceptibly less than the amplitude of the half period effect

According to Miller the full period effect is identified with that foreseen and calculated by Dr Hicks in a memoir of 1902[2] as a consequence of the small angular displacement μ of a few seconds of arc from its theoretical position that must be given to one of the mirrors to obtain the interference fringes

That this explanation of the full period effect cannot hold results at once if we consider that the Lorentz contraction ought to eliminate entirely any effect of the ether drift on the phenomenon of interference although it should influence only the half period effects It is then clear that the ether drift supposing it should appear is only able to produce half period effects that is displacements of the interference fringes that are reproduced identically every half turn of the interferometer This occurs of course whatever may be the effective adjustment given to the various parts of the instrument including the telescope

A direct demonstration may be derived from the results obtained by me[3] in 1925 in treating by a new method and in a complete manner the theory of the Michelson experiment following up the work of Righi[4] quoted by Miller in his memoir, which was interrupted by the death of the author My theory leads to the following formula for the displacement of the fringes when we take into consideration only the terms variable with the orientation of the interferometer given by the angle α

$$\Sigma = \frac{D\xi^2}{\lambda}\cos 2\alpha + \mu\frac{D^1\xi^2}{\lambda}\cos 2\alpha - \mu\frac{(D-D^1)\xi^2}{\lambda}\sin 2\alpha \quad (1)$$

where ξ is the velocity ratio λ the wave length *D* the effective length of the arm of the interferometer, D^1 the distance of the plane on which the observed inter ference fringes are localised Generally $D^1 = D$, that is the telescope is focused on the surface of the end mirror, in such cases the formula becomes

$$\Sigma = \frac{D\xi^2}{\lambda}\cos 2\alpha + \mu\frac{D\xi^2}{\lambda}\cos 2\alpha \qquad (2)$$

The first term here represents the Michelson effect, the others show that a supplementary effect of amplitude proportional to the angle μ or to the number of fringes visible in the field of view, may also be expected But such an effect is (*a*) of half period like the Michelson effect, (*b*) of amplitude μ ($\sim 2\times10^{-5}$) times less so that any possibility of an experimental verification is out of the question

The full period effect shown by interferometrical experiments *cannot be in any way justified by the classical ether drift theory* It is therefore the more important to know more thoroughly the characteristics of this effect which may be deduced from the rich observational material collected by Miller It may be either systematic perturbations introduced in the elaboration of the results of observation, or a phenomenon depending on another cause varying with the rotation of the interferometer perhaps the same that causes the difference between the results obtained by Miller and others who have experimented on the Michelson effect[4] and the unexplained anomalies that it represents[1]

Photography of the Infra-Red Solar Spectrum to Wave-length 12,900 A

WITH the aid of the new Agfa infra red sensitive plates (maximum of sensitivity 10 600 A) I have succeeded in photographing the solar spectrum to 12,900 A in the first order of a 3 m grating (dispersion 5 A /mm time of exposure 10 hours) The blackening of the exposure obtained does not alter appreciably from 12 400 to 12 900 A (end of the plate used), so that it seems easily possible to extend the limit quite considerably

The plates so far obtained show the water vapour absorption band at 11,300 A well resolved into its fine structure lines and extending about 1000 A to both sides It exhibits the same sort of complexity as the shorter wave length bands photographed and analysed by Mecke and his co workers[1], but is much more intense

In addition, there is a very interesting *atmospheric oxygen band* between 12,500 A and 12,750 A also of course, with very well resolved fine structure This band has already been observed with ordinary infra red apparatus and low dispersion by Ellis and Kneser[2] in the infra red absorption spectrum of *liquid* oxygen together with other bands, and they have identified it with a weak maximum in Abbot's bolometer curves of the solar spectrum That this band is really due to the oxygen molecule and represents the 'forbidden' transition from the ground level $^3\Sigma_g^-$ to the low $^1\Delta$ level first predicted by Mulliken[3] is rigorously proved by a preliminary fine structure analysis The observed structure shows that the selection rule $\Delta J = 0 \pm 1$ still holds for $^1\Delta - {}^3\Sigma$, but besides $\Delta K = 0, \pm 1$ (P, Q and R branches) transitions with $\Delta K = \pm 2$ occur with about equal intensity (S form and O form branches) The band on the whole is very much weaker than the ordinary atmospheric oxygen A band at 7600 A in agreement with the expectation that a $^1\Delta - {}^3\Sigma$ transition is more strongly forbidden than $^1\Sigma - {}^3\Sigma$ Preliminary constants for the $^1\Delta$ level are $\nu_e = 7881\ 6$ cm^{-1}, $B_e = 1\ 415$ cm^{-1}, $r_e = 1\ 220$ A A value for the vibrational frequency cannot be given because the 1–0 band observed by Ellis and Kneser at 10 600 A in liquid oxygen does not occur in the solar spectrum

A full account of this work will appear elsewhere

In conclusion it is a pleasure to acknowledge the kindness with which the firm of Agfa placed their remarkable new plates at our disposal

Velocity of Light

M E J GHEURY DE BRAY has directed attention to an apparent decrease in the velocity of light[1] I have recently tried to explain this on the basis of the theory of the expanding universe If the speed of light is a true constant independent of any variation in our unit of length then a doubling of the radius of the universe should cause the *measured* velocity of light to diminish by half If the radius of the universe doubles every K years then the velocity of light will be proportional to $(\frac{1}{2})^{t}$ where K is the unit of time Thus the logarithm of the measured velocity of light must be a linear function of the time I determined the two constants of such a function from de Bray's data and found that it represented the observations in a satisfactory manner I then solved this equation for the length of time it would take the velocity to diminish by half The time is of the order of 60 000 years which is considerably shorter than the value derived from a study of the recession of the external galaxies[2] Consequently this observed variation cannot be explained by the expanding universe theory unless we assume that the rate of expansion is much more rapid in the vicinity of the earth than it is at the distance of the spirals

It is also possible that the variation is not a continuous decrease but is a periodic function of the time A rough graphical analysis shows that the observations are well represented by

$$V = 299\ 885 + 115 \sin 2\pi/40\ (t - 1901)$$

The largest deviation is 21 km /sec and the others are all under 10 km /sec It is possible that these residuals could be improved by further adjustment of the constants

Unfortunately, the only evidence for a periodic variation is the observations in 1879 5, 1882 7 and 1882 8 These observations were made over short base lines, and are presumably not as accurate as those made over longer base lines If we reject them, as we may feel justified in doing, then the variation is a continuous decrease with the time. If we keep them, the variation is periodic. Either hypothesis beautifully represents the observations which are used. The unfortunate lack of observations in the periods 1883–1902 and 1902–1924 makes it impossible at present to decide between the two hypotheses. However, by 1941 the velocity will be 299 885 km./sec. if the variation is periodic, or 299 735 km./sec. if the variation is a linear decrease with the time. It is to be hoped that those who have been performing velocity experiments will continue their work until this matter is settled.

Static Charge on a Galvo-Millivoltmeter

A SOMEWHAT curious state of affairs has recently been brought to light in this Laboratory in connexion with a Unipivot galvo millivoltmeter. The needle of this instrument, which is used in the determination of *p*H values by the electrometer valve–glass electrode method, was found to behave erratically in respect of reproducing its maximum position. On closer examination it was found that, particularly in the case of certain individual operators, rubbing the glass cover of the instrument with the finger or even strong finger pressure produced deflection of the needle sometimes sufficiently violent to lift it from its suspension. Return of the needle, though not exactly to its former position, could usually be effected by tapping the glass.

Neither distortion of the case, nor capacity effects were present, and breathing on the glass cover was sufficient to restore a normal zero or maximum.

Although the case, in common with other vital parts in the electrical system, is normally earthed, it seems clear that a static charge on the glass is responsible for the phenomenon, and the necessity for bearing this possibility in mind when cleaning or removing dust becomes necessary with such an instrument is obvious.

Purification of Plant Viruses

THE following is a practical method of preparing a purified suspension of any of the X group of plant viruses from the extracted juice of the diseased plant.

Starting with volume *V* of extracted juice —

(*a*) *V* is cooled to 0° C. and diluted to 15 *V* with water at 0° C. Carbon dioxide gas is passed through the mixture at 0° C. for 30 minutes. This mixture is then centrifuged rapidly for as short a time as will give a clear straw-coloured supernatant, for example, 15 minutes at 3 000 r.p.m. The precipitate, which contains about one third of the original solids, is discarded.

(*b*) The supernatant is diluted to 200 *V* with water at 35° C. Carbon dioxide gas is passed through the mixture at 35° C. for 15 minutes. This mixture is then centrifuged for a considerable time, for example, 1 hour at 2 000 r.p.m. The supernatant is discarded.

(*c*) The precipitate is suspended in *V* c.c. distilled water at room temperature and centrifuged for a short time, for example, 15 minutes at 3 000 r.p.m. The precipitate is discarded. The supernatant is faintly opalescent but colourless. It contains most of the virus and practically no protein.

In (*a*) the flask is immersed in a freezing mixture. The best results are obtained when only a small amount of ice is formed in the solution and the temperature during the spinning does not go above 15° C.

In (*b*) cautious use of a micro burner will keep the temperature within half a degree of the optimum.

The long spinning of the large volume in (*b*) is the greatest fault of this method. The length of the spinning required to bring down a precipitate can be shortened to less than half an hour if higher speeds are used, also by adding a trace of aluminium sulphate or leaving the mixture in the cold overnight.

The method is a modification of one used by Warburg and Christian (1932)[1] to purify a water-soluble ferment. (The application of the method to virus studies was suggested by Prof. D. Keilin, to whom grateful acknowledgment is due.) The temperatures and dilutions given here have been determined after careful variation of all the constants. With virus X from infected tobacco plants, a final suspension can be produced which will infect 3 out of 5 *Nicotiana glutinosa* plants at a dilution of 1/50 000 as compared with 4 out of 5 with crude sap at the same dilution.

Inheritance of Habits

Do thought habits produce a physical change in the organism? I once asked a friend of mine who is a great experimentalist. He replied: "I don't know." "Does any habit produce a physical change?" He again replied: "I don't know." "Could he suggest any experiment to ascertain this point?" Once again he replied in the negative. I could see the discipline of science had produced a habit in him which the stimulus of my suggestion was not strong enough to overcome.

Were it not the case, then why do people find it difficult to change from one habit to another? It is not only difficult, but it is often accompanied by a feeling of positive pain. A transformation from one thing to another implies loss or gain of energy, and this energy must be summoned and given a direction before a change could be produced from one habit to another. Consider, for example, the difficulty many people are now experiencing in assuming the habit of a 24-hour clock.

Can habits be inherited? For anything to be inherited, the reproductive cells must be affected in a particular way. Experiments have been performed to settle this question. Mice have been trained to thread a maze of a particular configuration, and the offspring of such trained mice have been able to thread the same maze with the least difficulty and in the shortest time. This seems to indicate that acquired habits can be inherited. Recently experiments have been undertaken in Prof. E. W. MacBride's laboratory to see if the parthenogenetic stick insect of Ceylon could inherit the habit of eating plant *B* (which it can eat but does not usually do) instead of *A* which is its usual food plant. An account of this was published in NATURE of April 21 (p. 598). The result seems to show that such a preference can be *transmitted to the offspring*.

The difference between the maze threading experiment and that of compelling the acquisition of a new food plant is that in the former case no foreign matter is introduced into the body of the organism while *in* the latter case a different kind of food is introduced. In the former the habit is not accompanied by an obvious physical change in the organism while in the latter it is nothing but the acceptance on the part of the organism of a physical fact.

Whatever *may* be the *conclusions* drawn *from* these experiments, to determine whether a habit is inherited or not information on the following points is first necessary (1) Does habit produce a physical change (2) if so how can it be measured (3) in what *way is this change registered in the reproductive cells?*

It seems to me that the experiments so far undertaken have the same hit and miss character as those of the animal breeders before Mendel's time. For example it could not be predicted that a particular egg taken out of the lot produced by those insects that easily accepted the second food plant would result in an insect which showed a definite predilection for this alternative host plant.

Mimicry in Insects

PROF. T. D. A. COCKERELL points out[1] that parallelism and convergence are so frequent that they indicate deeply seated tendencies which find expression without any reference to immediate utility and that if mimicry is promoted by natural selection these resemblances are the raw material on which it works.

May I remark that the last words quoted are *misleading in their suggestion that* convergence *may play a large part in the causation of all the cases* of resemblance of one animal to another which are unfortunately classed together in the common usage of the term mimicry.

It is indeed possible that convergence (or arrested divergence) has played a part in the production of synaposematic resemblance such as Prof. Cockerell mentions in the case of wasps, although even in such cases there is no relation between the degree of resemblance and the degree of consanguinity. The similarity between species of the well known Burnet moths in England might, with justice be claimed as a good example. But this explanation, so simple and plausible, is of much too limited applicability to deal with the phenomena of mimicry. It cannot explain such examples of true Batesian mimicry as the pseudaposematic resemblance of a caterpillar to a snake which deceived Bates himself. Nor can it possibly apply to the analogous and equally deceptive procryptic resemblance of a caterpillar to a stick, or a moth to a bird dropping.

I find it difficult to understand how parallel development can have played any part in the production of a similar appearance in insects of different degrees of relationship by entirely different means, a phenomenon in mimicry too often left out of account in discussions. Upholders of the Darwinian explanation of mimicry are still awaiting an alternative which will embrace the above mentioned and many other phenomena which fall into line.

Pseudopodial Movements of Foraminifera

WORK of recent years has done much to elucidate the protoplasmic changes accompanying amoeboid movement. The endoplasmic streaming which is the most striking feature in the pseudopodium of an amoeba is not however present in most other rhizopods in which locomotion by creeping is less well developed and it seems that the time is ripe for a careful re-examination of the different types of pseudopodia.

In the Foraminifera the pseudopodia are long fine protoplasmic threads containing granules the size of which varies with the species and which are in rapid longitudinal movement. Commonly both centrifugally and centripetally moving granules are present simultaneously in the same thread often passing one another even though the thread may be less than a micron in diameter. Sometimes also a pseudopodium may be increasing in length at a time when the predominant movement of the granules is centripetal indicating a movement of the clear ground protoplasm independent of that of the granules. The granules are usually (perhaps always) near the surface of the pseudopodium and it is commonly supposed that the clear axial part of the protoplasm is of a more solid nature thus conferring stability on the fluid thread which otherwise would be expected to break up into drops owing to the fact that its length is often some hundred or more times its diameter.

Though it is at present impossible to give a clear account of the exact location of these various moving streams or of the nature of the motive force producing them or of the conditions of stability of the fluid pseudopodia the following preliminary observations have some bearing on these questions.

(1) In all the species examined by me the pseudopodia are enclosed by a relatively tough moving skin which can be demonstrated by various methods. Crawling ciliates may pluck the pseudopodium pulling and stretching it considerably without adhering to it. Small flagellates may even come to rest against a pseudopodium, be carried along passively for a considerable distance and then swim away without any sign of sticking. In transporting food, on the other hand, the pseudopodia show themselves to be very sticky. This may be due as Verworn[2] believed to active secretion of a sticky substance, but seems to be more probably due simply to penetration of the 'skin' by the captured object causing it to come into contact with the viscous internal fluid.

(2) The mean velocity of the granules in different pseudopodia of an individual at any instant is fairly

uniform and quite independent of the diameters of the pseudopodia Hence their movement cannot be compared to the flow of a viscous liquid in a tube

(3) The flow is not influenced in any way by contact with a solid substratum, a fact which is quite inconsistent with any simple interpretation based on surface tension differences Normal streaming of granules takes place even in pseudopodia having no free tip (that is, running from one part of the periphery of an animal to another part), and so can have nothing to do with conditions at the tip or with any kind of physiological gradient between the tip and the base There is likewise no evidence of any reversible sol gel process or of any contracting tube of plasma gel

(4) Injurious stimuli (chemical or thermal) cause the pseudopodia to break into liquid droplets, or, less commonly, into short rods These two reactions might appear to represent the effects of increased and decreased fluidity respectively but this explanation does not fit in with the known effects of the stimuli in question on other kinds of protoplasm In fact sometimes a single stimulus produces both of the reactions simultaneously in different parts of a single individual If the stability of the threads depends upon the presence of a relatively solid axial structure it seems strange that reagents which normally increase the viscosity of protoplasm should cause the threads to break into drops Cyanide causes a cessation of movement without any immediate disintegration so stability of the threads does not depend upon movement as suggested by Lepeschkin[2]

A Rapid Test for Pregnancy on *Xenopus lævis*

IN a recent communication Bellerby (1933)[1] has shown that injection of acid or alkaline extracts of bovine anterior lobe of the pituitary gland into female South African clawed toads (*Xenopus lævis*) produces extrusion of ova through the cloaca within 18 hours

The well known Zondek Ascheim test or its modification by Friedman, using the rabbit, is based on the occurrence in the urine of pregnancy of an anterior pituitary like gonado kinetic hormone

These considerations led us to investigate the possibilities of *Xenopus lævis* as a test animal for pregnancy The urine is detoxicated, precipitated and concentrated according to the method of Zondek (1930)[2] The aqueous extract is injected into each of six female South African clawed toads Twelve to eighteen hours later at room temperature, that is, about 18° C, a positive reaction is indicated by either (*a*) extrusion of macroscopic ova through the cloaca, or (*b*) post mortem examination of the animal (in the absence of ovulation), when one ovum or more is seen in either or both of the oviducts If (*a*) occurs in any one animal, post mortem examination of the remaining animals is unnecessary A negative test is repeated on a further six animals

At higher temperatures, for example, about 27° C, the reaction is speeded up considerably and ovulation has already occurred so soon as 5–6 hours after injection

In a series of 97 cases investigated by this method to date, 52 correct positive and 45 correct negative findings have been recorded

Xenopus is a suitable test animal as it does not ovulate spontaneously under laboratory conditions As a matter of fact, in about 250 toads fresh from the ponds examined during the breeding season, no ova were detected in the oviducts (Zwarenstein and Shapiro 1933)[3] However, during the breeding season (July to September in South Africa) as an additional precaution it is necessary that the test animals from the ponds should be isolated under laboratory conditions for at least one week and controls killed and examined

We have observed that if the toads have been maintained under laboratory conditions for longer than three to four weeks, they appear to undergo a desensitisation to the urinary prolan, when incorrect negatives may be obtained The laboratory age of the test animals should therefore not exceed three to four weeks

The advantages of the test are as follows —

1 The test animal is cheap easily available and inexpensive to maintain

2 It is not necessary in the majority of cases to kill the test animal as it is with rats mice and rabbits

3 The extremely short time taken for the test—16 18 hours at room temperature (18°–20° C) A technique for further shortening the post injection latent interval is being investigated

4 The simplicity of the end reaction—extrusion of easily visible ova through the cloaca or their presence in the ducts In Amphibia extrusion of the ova is a sufficiently obvious and unequivocal phenomenon

5 Small volumes of aqueous extract may be injected into the test animal in a single dose repeated and divided doses being unnecessary

Although extrusion of ova does not occur in *Rana* after injection of anterior pituitary extract[4] a reaction is obtained in the oviducts and this indicates the possibility of using *Rana* also as a test animal

In collaboration with Dr A I Goldberg the test is being applied in the investigation of cases of endocrine anomalies

Egyptian Head-rests Among recent acquisitions noted in the *British Museum Quarterly* vol 8 pt 3 is a small collection of Egyptian objects of exceptional interest which are described by Mr S R K Glanville Among these are two head rests of which one of limestone is reported to have come from Dair Mawas on the other side of the river from Al Amarnah It is remarkable both for its form and its decoration It is adapted from the type with octagonal fluted column found commonly in the Eighteenth Dynasty and more rarely in the Fourteenth The space between the horns of the rest proper and the base has been only partially cut away so as to leave a panel of stone on either side of the shaft This minimised the risk of breaking off the tips of the rest These panels have been decorated in low relief with four figures one on each side of the shaft On what is probably the front of the head rest two figures of Bes face inward to the support The figure on the right brandishes a serpent in his left hand and carries a spear in the other Two more snakes are held beneath his teeth He wears the lotus flower often shown on the head of Bes and Taurt in the Eighteenth Dynasty A hieroglyphic inscription down the centre reads Good Sleeping in the West the Land of Righteousness by the Royal Scribe Qenherkhepeshef justified On the back of the rest a griffin on the left with lotus flower head dress faces a lioness eating a snake Both rest their feet on conical supports and are armed with knives Two more inscriptions run down the edges of the panels of which one survives in a mutilated state The four figures are reminiscent of those on carved ivory wands of the Seventh to Eighteenth Dynasties the use of which is still debated If the head rest is to be dated to the Eighteenth to Nineteenth Dynasty this is the earliest representation of Bes with a spear giving him a warlike character The magical character of the figures and the inscriptions indicate that the head rest was part of the tomb furniture and not for ordinary use

Anthropometric Technique A critical examination of the methods of anthropometric measurement on the living has been made by Dr C B Davenport Dr Morris Steggerda and Dr William Drager (*Proc Amer Acad Arts and Sci* 69 6) Errors in anthropometry are both extrinsic and intrinsic Among extrinsic errors while the apparatus used may be regarded as standardised the determination of particular landmarks is a frequent cause of error A matter insufficiently investigated as yet is the error due to differences in posture of the subject and the fluctuations due to his or her psychological or physiological state It is known that there are considerable differences according to the time of day at which the measurements are made Within limits anthropometry is a form of psychometry Variation due to differences in pressure on the skin in taking measurements has not been sufficiently considered With the view of testing the effect of these sources of error forty nine measurements were made repeatedly under certain controls It was found *inter alia* that stature and sitting height were significantly greater in the morning than in the evening A woman's indoor clothing does not appreciably affect the significance of the measurement though it may obscure the location of the point measured The diameters of the head are easily measured with a probable variation in repeated measurements of less than 1 mm Certain dimensions have a high variability with a probable error of single measurements of 5 mm or more These are waist girth chest girth projective arm measurements from the floor and trochanter breadth It was found that the subject measured was significantly larger on her left side than her right As an intrinsic error it was found that in the personal equation the percentage inaccuracy varies greatly being low in large dimensions The inaccuracy is partly inherent but practice leads to increased precision

A New Trout from California. Mr John Otterburn Snyder has recently described a new species of cut throat trout *Salmo seleniris* (*Proc Californian Acad Sci* Fourth Series 20 No 11 1933) This has been found in certain headwaters of Silver King Creek a tributary of East Carson River which is part of the Lahontan drainage area The habitat is restricted by an impassable fall to the creeks of Fish Valley in the high Sierra of California The author states that it is an isolated variant of *S henshawi* differing markedly in the absence of spots from the body the retention of parr marks to maturity and the relatively smaller and more numerous scales The differentiation of this form from the more generally distributed parent species is directly parallel with that of the golden trouts west of the Sierra as they differ from the rainbow in a reduction of the spots the retention of parr marks and a notable increase of the number of scales There is little variation from the type in this trout

Regulation of Blood Salinity in Aquatic Animals Vol II Nos 1–6 of the Sydney University Reprints (Series 13 Zoology 1933) contains several papers conspicuous among them being Prof Dakin s and Miss E Edmonds work on the regulation of the salt contents of the blood of aquatic animals and the problem of the permeability of the bounding membranes of aquatic invertebrates reprinted from the *Australian Journal of Experimental Biology and Medical Science* 8 1931 The authors have found new subjects for investigation in the mangrove swamps setting up a temporary summer laboratory actually on the edge of the swamp in order to keep the animals in as healthy a condition as possible *Helaecius cordiformis* lives in the mangrove swamp not far from the sea in water of high salinity but subject to occasional freshenings of considerable extent after rain It is able to regulate the blood salinity in the sea water which is diluted with fresh water the blood being more saline than the surrounding medium the difference between the blood and the external medium becoming greater as the latter approaches fresh water It seems however to show a greater independence than other marine invertebrates so far investigated in that the blood tends to retain its normal constitution when the external sea water is made more concentrated It is shown that the changes in the blood salts which accompany changes in the outer medium are likely to be due to movements of salts or their ions inwards or outwards *Onchidium chameleon* increases in weight in diluted, and decreases in concentrated, sea water. Changes in the salinity of the external media are accompanied by changes in the body fluids, but the body wall acts more like a semi-permeable membrane and water movements through it are more facile than the passage of salts, which, however, also takes place.

***X*-Chromosome of *Drosophila*.** Through the work of Muller, Painter and others it is now recognised that about half of the *X* chromosome in *Drosophila melanogaster* is 'empty' of genes, and that this inert region is homologous with the *Y* chromosome. Mr. S. Gershenson (*J. Genetics*, 28, No. 2) has recently used for further study a strain with an *X* chromosome obtained through crossing over between two differently inverted *X* chromosomes, which therefore carries a duplication and a deficiency. The condition is lethal in *XX* females, but *XXY* females are viable. It was also found that the deficiency included the gene for bobbed bristles, but no other known genes. In males carrying this *X* chromosome, there was failure of synapsis between the *X* and *Y* in more than 60 per cent of the spermatogonia. In oogonia having this chromosome, one *X* was shown cytologically to be much shorter than the other. It is pointed out that such deficiency in the *X* would weaken the synaptic affinity between the *X* and *Y* and as a result the *XO* type of sex determination could be derived from the *XY* type. This work confirms the general views regarding the inertness of the *Y* chromosome and its similarity to the inert portion of the *X*. It also shows that genetical deficiency means the real absence of the corresponding portion of the chromosome.

Classification of Sesame. A recent study of the sesame (*Sesamum indicum*, L.) by Hildebrant (*Bull. App. Bot. Gen. and Plant Breeding*, 4, 4; 1932, Institute of Plant Industry, Leningrad), is based on 500 samples of seed collected by various expeditions; more than a third of these came from Central Asia and Asia Minor. As a preliminary to classification, the author deals with the variation in the characters of the plant in relation to geographical distribution. The species is divided into two sub-species according to the number of carpels in the capsule. A morphological basis is used for division into varieties. The mass of sesame in all countries is composed mainly of two varieties, the other varieties occurring mostly in mixtures with these varieties. The author considers Africa to be the primary centre of origin of the species, with India and Japan as secondary centres. Palestine appears to be the centre of high oil-yielding strains, the percentage of oil diminishing as one goes farther away from that country.

Nutrition of the Angiosperm Embryo. A very interesting general account of this subject is presented by René Souèges in the *Revue générale des Sciences*, 45, No. 5, of March 15. He shows how practically every tissue, either of the ovule or of the mature embryo sac, may be modified in ways that suggest a definite contribution to the nutrition either of the embryo sac itself or of the maturing embryo. Sometimes these adaptations take the form of remarkable haustorial constructions which are carried deeply into the chalazal end of the ovule or, in some cases, into the placenta by way of the micropyle. Although there may be little doubt that these structural features upon which emphasis is laid, contribute to the nutrition of the developing embryo, it must be admitted that the paths along which such transference of material takes place and the mechanism of translocation remain as yet entirely obscure.

Varieties of *Lilium candidum*. The *Gardeners' Chronicle* of April 7 contains a short article by the Abbé Souillet on *Lilium candidum* and its Varieties. This particular lily originated in Asia Minor, and in the wild state is extremely fertile, though small-flowered. The varieties *Charles X*, *peregrinum Salonica*, *spicatum*, *foliis variegatis* and *purpureo striatum* are described in detail, and particular attention is given to stability of form and fertility. It is interesting to note that the Abbé Souillet is attempting to breed a red *Lilium candidum* by crossing the female sterile variety *purpureo striatum* with the variety *Charles X* as the seed parent. Many of the varieties are subject to severe attacks by the fungus *Botrytis elliptica*.

Magmatic Problems. In his presidential address to the Geological Society of Washington, Dr. C. N. Fenner describes some striking cases of assimilation which seem to be incompatible with the requirements of the well-known theory of crystallisation differentiation advocated by Bowen and others (*J. Wash. Acad. Sci.*, 24, 113–124; 1934). According to this theory rhyolitic magma is produced by separation of crystals from a more basic parental magma, and it is therefore the coolest liquid of the series. It follows that if rhyolitic magma should engulf fragments of basalt it should normally be no more able to melt them or take them into solution than a cooling salt solution that had deposited crystals could redissolve those crystals on continued cooling. Dr. Fenner gives ample evidence, however, that both in the Katmai region and in Yellowstone Park, rhyolite magma has been able to dissolve large amounts of basic andesites and basalts. In one of the Yellowstone occurrences, assimilation produced homogeneous looking andesitic rocks. Analyses of two of these hybrids showed that they were respectively 30 per cent basalt plus 70 per cent rhyolite, and 69 per cent basalt plus 31 per cent rhyolite. Evidently there were heat reserves in the acid magma not recognised in the theory of crystallisation differentiation. In the Katmai region not even the reaction principle can be invoked, for here no precipitation of new minerals occurred. The contaminated magma became wholly liquid. The problem of heat supply is a difficult one, but it may be suggested that if the rhyolites were products of refusion in depth, the difficulty would be largely met.

Forecasting Rainfall in China. A paper entitled "China Rainfall and World Weather" by Chang Wang Tu (*Mem. Roy. Met. Soc.*, 4, No. 38) deals with the problem of forecasting the seasonal rainfall of China from statistical relationships—established as the result of a special inquiry—between the quantity to be predicted and the values of certain meteorological elements in various parts of the world previous to the rainy season. The method followed is that devised by Sir Gilbert Walker and others, who demonstrated the existence of large-scale fluctuations known as the North Atlantic, the North Pacific and the Southern oscillations. In this paper, China has been divided into four climatic regions: (1) the North China coast, (2) the Yangtse delta, (3) the Yangtse valley and (4) the South-east China coast. This division was found to be very necessary, the maps showing the correlation between the rainfall of the four divisions and contemporary deviations of pressure from normal in different parts of the world being very different The final achievement was the working out of equations for the seasonal rainfall using connexions with three or four distant centres, giving the equivalent of single total correlation coefficients having the following values North China coast (rainfall), June–September, 0 78, Yangtse delta, June–August, 0 62, Yangtze valley, May–August, 0 68, and South-east China coast, May–August, 0 68 The enormous loss of life and damage to property caused by floods in North China is well known, and some assistance towards prediction of these disasters will obviously result from any success in foreshadowing the seasonal rainfall For purposes of prediction a correlation coefficient of 0 78 is by no means negligible, results of practical value may therefore be hoped for in time

The Production of Positive Electrons Chadwick, Blackett and Occhialini have described a number of experiments on the production of positrons by various radiations (*Proc Roy Soc*, A, March) The positrons were examined in the usual way with a Wilson chamber in a magnetic field Positrons were produced in fair number when the hard γ rays of thorium C″ passed through lead, and the upper limit of their energy spectrum was consistent with the Dirac view that the energy of the γ ray was used in the creation of a negative and positive electron of approximately equal mass (requiring together about one million volts) and that the remaining energy is distributed between these particles By comparing the curvature of the positron tracks with the recoil tracks produced by Compton absorption of the γ rays, it was possible to get a fairly accurate upper limit to the positron energies, and accepting the Dirac view, the mass of the positron is found to be very close to that of the electron The probability of positron production in lead by the 2 6 million volt γ rays from thorium C″ may be as high as 0 2–0 3 of the probability of the liberation of an electron by the normal processes of scattering and absorption, and it is interesting to note that this is just sufficient to account for the anomalous absorption discussed by Gray and Tarrant and others (see NATURE, 133, 618, April 21, 1934) Further experiments showed that a large number of positrons come from a bare thorium active deposit source, as has previously been found by Thibaud, and it is probable that they have their origin in the radio active atoms themselves Experiments with the mixed radiation obtained by bombarding beryllium, boron or fluorine with α particles seemed to indicate that the neutrons as well as the γ rays may produce positrons in their passage through lead, though this may be an indirect effect in which a γ ray is first produced by the neutron

International Atomic Weights The report of the Committee on Atomic Weights of the International Union of Chemistry is now available (*J Chem Soc*, April, and *J Amer Chem Soc*, April) In the case of carbon, a higher value, 12 011, has been reported, but the Committee awaits further confirmation A long discussion of potassium is given, and the value 39 096 is adopted The value for arsenic has been changed from 74 93 to 74 91, and that of selenium from 79 2 to 78 96 Tellurium is changed from 127 5 to 127 61 The new value for cæsium, 132 91, agrees exactly with Aston's corrected value Erbium and ytterbium are changed to 165 20 and 173 04, respectively, osmium to 191 5, thallium is given the value 204 40, agreeing with Aston's 204 39, and some recent values for isotopes of lead are reported Although both Baxter and Alter and Hönigschmid, Sachtleben and Baudrexler obtained a value 207 21 for common lead, the value given in the table is 207 22

Dielectric Constants of Polar Solutions Observations on the dielectric constants of solutions of α amino butyric acid and glycine in water show that the dielectric constant is a linear function of concentration (mol/litre) to the highest concentrations studied (Wyman, *J Amer Chem Soc* March 1934) For the same solute in different solvents (water, ethyl alcohol solutions, urea solutions, α aminobutyric acid in glycine solutions and vice versa) the increment δ in dielectric constant per mol of ampholyte added to the solution is practically constant whilst the dielectric constant of the solvent varies considerably In polar solvents, therefore, the dielectric constant is a nearly additive property The results are interpreted by the assumption that the polarisation per c c is linear in concentration which implies that the effective field F shall be the same as the intensity E, the contribution of polarisation, F_2, being equal and opposite to the polarisation, F_3, due to dielectric inside a small sphere surrounding a molecule F_3 is usually neglected in dielectric theory Thus $(\epsilon \quad 1)/3 = p$ (polarisation per c c) is obtained in place of the classical equation $(\epsilon - 1)/(\epsilon + 2)\rho = p'$ (polarisation per gram, ρ = density) This leads to much larger values for the polarisation when ϵ is large, and these are supposed to represent better the assumed polarisations of zwitter ions of ampholytes

Automatic Arc Welding The use of the electric arc for welding metal plates is rapidly increasing and doubtless affects the employment of riveters Many attempts have been made to develop an automatic arc welder, which will still further affect the market for skilled manual labour The automatic welder feeds the electrode over its required path by a special mechanism The automatic control of the electrode feed keeps the arc constant so that even an unskilled labourer can work it Continuous operation is possible as the electrode wire is coiled on a reel This avoids the dangers of porous welds, which are apt to occur with hand welding owing to the necessary interruptions for changing the electrodes With the machine, the current enters the electrode close to the arc and thus larger currents can be used In the *Asea Journal* of January (Allmänna Svenska Elektriska A B), a full description is given of the new Asea Ipsoweld automatic welder The drawbacks to earlier designs of automatic welder seem to have been overcome In particular this machine can weld longitudinally, transversely and round circles and other forms of curve It is suitable for either indoor or outdoor use A rough estimate is given that an automatic machine can replace two or three hand welders Placing the yearly cost of one hand welder at £200, the saving per year would be at least this sum It is concluded that an automatic welding plant working full time pays for itself in two years Carbon electrodes only burn at the rate of eight inches per hour and the amount of filling wire used per hour is about 4½ lb

Some Exhibits at the Royal Society Conversazione

THE first of this year's conversaziones at the Royal Society, held on May 9, produced as usual a number of interesting exhibits and demonstrations Several have been the subject of recent communications in our correspondence columns, and descriptions of some of the remainder taken from the programme are printed below

Mr George H Gabb showed a telescope of 1646 by Maria de Rheita, which is the earliest known dated optical instrument in the world Maria de Rheita (1597 1660) a Capuchin Bohemian monk whose name was Antonius V Schyrle before his monastic conversion was the first to invent a terrestrial telescope with an image erecting eyepiece of three lenses He described its construction in a folio work Oculus Enoch atque Eliæ', published in 1645 a copy of which is in the library of the Royal Society No example of his telescopes was hitherto known to have survived

Mr Henry Balfour showed an interesting collection of stone implements from Tasmania from the fashioning of which the culture of the Tasmanians is regarded as corresponding to that of Cromagnon man in Europe

Mr R W Paul exhibited a simple apparatus for prolonged artificial respiration, which was designed at the suggestion of Sir William Bragg It has already been used in one case of progressive muscular atrophy unceasingly for a period of eight months, and has prolonged the life of the patient, who, without aid, would die in less than two minutes It comprises three main units (1) an inflatable air bag, or belt encircling the chest, (2) a pulsator which rhythmically inflates the air bag, and (3) a controller governing the speed of the pulsator The pulsator on its upward stroke inflates the air bag causes a pressure to be applied to the chest and squeezes air out of the lungs On the downward stroke of the pulsator, air is released from the bag the chest resumes its normal position and air is inhaled The volume of air inhaled can be varied by altering the pressure in the air bag The apparatus is silent and automatic in operation, simple to adjust and easily transportable

Dr W R Jones showed microscope preparations illustrating his view that minerals other than uncombined silica can cause silicosis Sections of many silicotic lungs show innumerable acicular fibres of sericite, a silicate of aluminium and potassium, which greatly outnumber the quartz particles In the Kolar Goldfield India silicosis is rare, and sericite is also rare in the Kolar quartz, on the other hand, the gold bearing rock worked on the Rand contains sericite and many cases of silicosis occur

The Entomological Department, Rothamsted Experimental Station (Dr C B Williams and Mr D Morland) showed a light trap, which catches and kills the insects attracted to it at night and sorts them into eight groups according to the time of night at which they enter The captures are correlated with various weather conditions including temperature, wind, humidity, the cloudiness of the sky and the duration of moonlight A photoelectric method of measuring the cell space ratio in woods was demonstrated by the Forest Products Research Laboratory The quantity of light transmitted by a suitably stained micro section of the wood is measured as a percentage of the total quantity of light falling on the section By adjusting the magnification of the projected image of the section measurements may be made either on an integral number of annual rings, giving an average value of the cell space ratio, or on a small area confined to the spring or summerwood separately Dr F G Gregory and Mr H L Pearse showed a self recording apparatus for measuring changes in aperture of stomata A glass cup attached to the lower side of a leaf by a gelatine washer is connected in series to a constant pressure aspirator through a variable capillary resistance, and air is thus drawn through the stomata The pressure between the leaf and the resistance is recorded by a manometer, the varying level in which interrupts a beam of heat focused on a linear thermopile

Some silica glass from the Libyan Desert was shown by Dr L J Spencer (Department of Mineralogy, British Museum (Natural History)) This material was recently discovered by Mr P A Clayton during the work of the Egyptian Desert Surveys in the unexplored region bordering on Italian Cyrenaica about 500 miles south west of Cairo The material is a nearly pure silica glass containing SiO_2 97 58 per cent, pale greenish yellow in colour and makes an effective gemstone It is quite distinct from the fulgurites formed by lightning It resembles most closely the still problematical tektites, the presence of a trace of nickel suggests a relation to the silica glass found around meteorite craters

Sir Gilbert Walker and Mr A Graham demonstrated the formation of artificial clouds If a layer of liquid or air at rest is heated below or cooled above the vertical instability will produce motion in polygonal cells, but if the fluid moves with considerable shear there will be longitudinal cells parallel to the direction of the shear In air, a slow shear produced by sliding along the glass top of the containing trough produces transverse cells and an intermediate velocity a rectangular pattern These can be identified with cloud forms Prof E J Baldes demonstrated micro methods of measuring vapour pressure It can be shown theoretically that the vapour pressure thermopile consisting of 50 couples of constantan silver, with wires of high thermal conductivity, is inefficient and that similar measurements can be made with a single thermocouple The technique of measuring vapour pressures of small drops of liquid (1 mgm or less) suspended from the junctions of a thermocouple was demonstrated Mr R C Brown showed some methods of studying capillary waves Ripples produced on a liquid surface by a point or line-source maintained by a valve oscillator are made to appear stationary by intermittent illumination of the same frequency The frequency is determined by connecting an Osglim lamp across the oscillator output and allowing this to illuminate a stroboscopic disc controlled by a 50 cycle tuning fork Thus measurements of wave length and amplitude can be made over a range of frequency, the validity of Kelvin's equation tested, and surface tensions measured It is also shown that a liquid surface over which ripples are passing may be used as a plane reflecting diffraction grating for visible light

Prof E G Coker and Prof A V Hill combined to show some experiments on thermo elasticity The adiabatic thermal changes during extension and compression of materials have long been known, but measurement has been difficult By employing a radiation thermopile and a galvanometer of high sensitivity and short period the thermal effect of loading a specimen can be read on a scale, or recorded photographically, in a few seconds The stresses in rigid materials can be measured with an accuracy comparable with any other known form of measurement, and strange to say, the order of the measurements depends on the coefficient of expansion of the material employed and not on Young's modulus and Poisson's ratio as in some other methods Steel, brass, vulcanite and other bodies possessing a coefficient of expansion or contraction confirm this In cases of plane complex stress, the measurements give the sum of the principal stresses The adiabatic compression of various liquids, including water, has also been measured in this way, at pressures up to 1,500 lb per sq in and the simple thermo electrical arrangements used are such that the range of pressures can be extended almost indefinitely

The Metropolitan Vickers Electrical Company Ltd , exhibited a portable noise measuring apparatus, working on the aural balance principle It consists essentially of a valve oscillator, a calibrated attenuator and a telephone earpiece The oscillator generates current at 800 cycles which is fed to the telephone through adjustable attenuators The apparatus is calibrated so as to indicate directly the intensity of the 800 cycle tone in the telephone in decibels above threshold of 0 0003 dynes/sq cm , measured in the ear or 0 00021 dynes/sq cm , measured in free space The observer places the telephone on one ear and presents the other to the complex noise to be measured He then adjusts the attenuators until he judges the loudness of the 800 cycle note heard in the telephone to be equal to that of the complex noise The equivalent value of the complex noise is then read in decibels above threshold from the settings of the attenuators

A fractional seconds chronograph was shown by Mr E A Nehan (Mathematical Department, Imperial College of Science) This instrument is designed to record visibly on paper tape, 0 01 sec at 1/10th inch scale, up to four events simultaneously A tuning fork controls a synchronous motor, which through a 3 speed gear gives motion to a printing train and paper feed at the selected speed Four inking pens record any event, translated as a simple make and break circuit, which mark on the tape is squared down to the time scale printed on the tape The machine is portable, self-contained and worked from a 12 volt accumulator Mr J Harvey, of the same Department, showed an integrator By rolling a horizontal spur wheel on a rack in one direction and moving the rack perpendicularly, the axis of the wheel can be made to trace a curve whose Fourier coefficients are required The wheel makes n turns over a range of rack representing $0 - 2\pi$ On a horizontal arm fixed to the axle of this wheel, is a wheel which rolls on the paper and registers the coefficients a_n and b_n Six harmonics can be found The mechanism is adapted to find area, and first and second moments of area about an axis, on the principle of Amsler's moment integrator

The National Physical Laboratory (Mr R A Watson Watt, Mr J F Herd and Mr L H Bainbridge Bell) showed a cathode ray tube which has been made to serve as a magnetic compass The cathode ray beam is deflected by the earth's magnetic field and may therefore be used as a compass needle free from inertia In the present instrument light signals controlled by collector electrodes in the tube indicate any change in the magnetic bearing of the platform carrying the tube Changes of a small fraction of a degree can be indicated Among the exhibits by the Director of Scientific Research Admiralty was an apparatus which enables the deaf to hear by bone conduction Amplified currents from a microphone are supplied to a coil wound direct on to a straight nickel iron wire which has a high magnetostriction coefficient The wire vibrates with the frequency of the current and the vibrations may be transmitted to the cochlea through the bones of the head or jaw either by clenching the wire in the teeth or by pressing it on the mastoid bone behind the ear The same Department also showed an automatic radio direction finder This instrument is of the Bellini Tosi type comprising two crossed frame coils and a goniometer the search coil of which is rotated by an electric motor The goniometer is connected to a radio receiver followed by a special rectifier and relay system which reverses the direction of the electric motor whenever the high frequency current in the search coil increases, thus, since the direction of rotation of the search coil is reversed whenever the minimum is passed, the search coil hunts a position at minimum

---

Interpretation of Evidence for the Recession of Nebulæ

AT Oxford on Tuesday, May 8, Dr Edwin Hubble, of the Mount Wilson Observatory, delivered the Halley Lecture on 'Red Shifts in the Spectra of Nebulæ" As is indicated by the title the lecture was concerned with a non speculative account of those investigations, largely due to Dr Hubble himself, which have led to the far reaching speculations of de Sitter, Eddington, Milne, and others on the expansion of the universe After a masterly account of the use of Cepheid variables in determining the distances of the nearer extra galactic nebulæ, of the statistical methods involving the intrinsic luminosity of the average nebula for the distances of the remoter objects, and of the radial velocities or red shifts measured by Slipher and Humason, Dr Hubble developed in full the velocity-distance relation which bears his name For the 150 nebulæ of which spectra have now been obtained and which lie within a sphere of 150 million light years radius, he was able to show that the red shifts, expressed as velocities, increase linearly by roughly one hundred miles per second for each million light years of distance, further, he was able to show that the difference between the linear relation for isolated nebulæ and for clusters of nebulæ is wholly the effect of selection, and thus to harmonise the results from all observed nebulæ

The lecture concluded with an attempt to interpret the observed red shift on the basis of the available observational material alone If the red shift is produced by some unspecified cause, Doppler effect being thus expressly excluded, then the brightness of the nebula will be reduced by the factor $(1-d\lambda/\lambda)$ because each quantum carries less energy, and also roughly by the same factor again because the weaker ultra violet part of the spectrum is displaced into the photographic region (the correction from bolometric to photographic magnitude). If, on the other hand, the red shift is due to an actual velocity of recession, then not only does each of the two previous effects reduce the brightness in the ratio $(1-d\lambda/\lambda)$, but also there is a reduction by a similar factor because the nebula is receding and fewer quanta reach the photographic plate per second. From counts of nebulæ made to five different apparent magnitudes, the numbers of nebulæ in each of the five corresponding spheres of increasing radius can be found, the radius of each sphere being given by the intrinsic luminosity of the average nebula and its apparent luminosity, corrected either by $(1-d\lambda/\lambda)$ for pure red shift, or by $(1-d\lambda/\lambda)^2$ for red shift interpreted as velocity of recession.

These counts indicate that, if the red shift is due to velocity, then the number of nebulæ per unit volume must increase rapidly with increasing distance —a somewhat startling result; on the other hand if the red shift is not produced by a Doppler effect, then the counts indicate that the nebulæ are uniformly distributed over the sphere of 350 million light years radius which is within the range of the 100 inch reflector at Mount Wilson. While this particular result was not stressed by Dr. Hubble, he concluded by pointing out how the completion of the 200 inch reflector will enable such counts and velocity determinations to be extended over a far larger volume of space, and will thus permit a definite interpretation of the red shift, either as due to velocity of recession, or as due to some other yet unknown physical cause.

Decrease of the Barn Owl in England and Wales

PRECISE knowledge of the standing of particular birds in Britain should result from the increasing number of national censuses which have been initiated in recent years. Where the statistical information is thorough, it will form an invaluable basis of comparison with similar data gathered in future years; even where statistics have been dropped and reliance is placed upon the opinions of many observers scattered over a wide area, the consensus of opinion may still be a reliable guide to the fluctuations of the population.

Both kinds of information have been utilised in a census of the barn owl in England and Wales, made between May and December 1932, the results of which have been summarised by G. B. Blaker in an attractive pamphlet published by the Royal Society for the Protection of Birds. By making reasonable estimations in areas where direct information was not forthcoming, the author assesses the total breeding population of barn owls (*Tyto alba*) in England and Wales at 12,000 pairs. Non-breeding birds averaged one to every 50 square miles, so that the total adult population of barn owls in the summer of 1932 was about 25,000 individuals.

The absolute number is not so important as knowledge as to what relation it bears to that of former years, and here the statistics of one season, which contain no time element, cannot help. But putting one scrap of evidence regarding former conditions with another, Mr. Blaker has no difficulty in coming to the conclusion that the fears of those who suspected a serious decline in the numbers of the barn owl are justified. "From all districts in central and southern England the reports brought the same tale—fewer occupied nests than a few years ago. In parts of Essex and Suffolk the decline was less marked, while in Devon and Cornwall the barn owl seems to be holding its own. Northumberland, Cumberland and Westmorland are the only counties to record an increase."

The decline in numbers over the greater part of the country appears to be no new thing: it has been noted for the last thirty or forty years. The disturbing point is that it has been speeding up during the last six years or so, until it has reached a point when so far as the records can be interpreted, about four per cent of the population (or 1,000 birds) disappears annually; this, of course, over and above the annual wastage which would keep the population at a steady number.

Several factors contribute to the falling numbers of the barn owl. Nesting sites are fewer, partly because church authorities object to the occupation of towers and belfries by the ghostly 'cherubim', and fence the old nesting holes with wire entanglements; partly because modern barns with corrugated iron roofs do not offer openings like the 'owls' windows' of the old type. Food is probably more scarce since 'rat weeks' were instituted and the farmer has generally intensified his campaign against vermin. This has had a further effect in that the methods of destroying rats by poison has, the evidence indicates, resulted in the poisoning of owls which have devoured living but poisoned rats. Finally, there is the deliberate destruction of barn owls by people who should, but seemingly still do not, know better.

The author suggests, without definitely formulating the charge that inefficiency of the Wild Birds Protection Acts is involved in the decline of the barn owl, but he states quite clearly the crux of this matter, namely, that it is in the administration of the law that the weakness, if any, lies. Were the critics of the present Birds Protection Acts to report the offences and insist with witnesses upon the prosecution of the offenders (and they seem to be well supplied with instances of law breaking), they would be making a contribution of value to the working of the law, and making no more of a contribution than the laws in question expect and make provision for them and other well disposed citizens to make. But indeed, with regard to the barn owl, it is legitimate to ask whether the probability is that its present status would have been better or worse had there been no bird protection laws, and further why, if the law is a source of evil, the brown owl should have increased in numbers so enormously in the years when the barn owl has been declining? J. R.

University and Educational Intelligence

BIRMINGHAM.—Mr. Stuart McDonald has been appointed lecturer in pathology in succession to Dr. F. W. M. Lamb, who has been appointed professor of forensic medicine at Cairo.

CAMBRIDGE.—Dr. W. W. Watts has been appointed to represent the University at the centenary of the Edinburgh Geological Society on September 3–4.

At St John's College, A V Stephens has been elected to a fellowship Mr Stephens gained a first class in the Mechanical Sciences Tripos in 1930 with distinction in aeronautics and the award of the Seeley Prize For the last three years he has been engaged in scientific research at the Royal Aircraft Establishment, Farnborough, and has conducted experiments and published papers on the spinning of aeroplanes

In Congregation on May 11, the degree of Sc D was conferred on John Read (Emmanuel College), professor of chemistry in the University of St Andrews and formerly professor of organic chemistry in the University of Sydney Prof Read is the author of publications on organic chemistry and historical chemistry, and is known also for his original investigations on stereochemistry, terpene chemistry, and the chemistry of Australasian natural products

SHEFFIELD —Mrs Edward Mellanby has been appointed honorary lecturer in the Department of Physiology

---

The following Commonwealth Fund Fellowships, among others, tenable by British graduates in American Universities for the two years beginning September 1934, have recently been awarded R N Arnold (Glasgow and Sheffield) to the University of Illinois, in engineering , Stewart Bates (Glasgow and Edinburgh), to Harvard University, in economics , J H Brown (Glasgow and Oxford), to the University of California, in philosophy , Philip Chantler (Manchester) to Harvard University, in economics , C J M Fletcher (Oxford) to the University of California, in chemistry , E N Fox (Cambridge), to the University of Michigan, in engineering , E G Hancox (Liverpool and Imperial College of Science and Technology), to the University of Arizona, in geology , Joseph McGinn (Armstrong College, Newcastle), to Harvard University, in business administration , F G W Smith (Imperial College of Science and Technology), to Princeton University, in zoology , A D Thackeray (Cambridge), to the California Institute of Technology, in astrophysics , J C Trevor (Oxford), to Northwestern University, in anthropology , A G M Weddell (St Bartholomew's Hospital Medical College), to the University of Rochester, in medicine , Shaun Wylie (Oxford), to Princeton University, in mathematics

The following have been appointed to fellowships tenable by candidates from the British Dominions M M Burns (New Zealand and Aberdeen), to Cornell University, in agriculture , James Melville (New Zealand and Imperial College of Science and Technology), to Yale University, in biochemistry

The following have been appointed to fellowships tenable by candidates holding appointments in Government service overseas J D W A Coles (Witwatersrand and Department of Agriculture, South Africa), to Washington University, in veterinary science , Dr R H Le Pelley (Imperial College of Science and Technology and Department of Agriculture, Kenya Colony), to the University of Illinois, in entomology , H E McMillan (Saskatchewan and the Department of Agriculture, Canada), to the University of California, in entomology , E A Moore (Bristol and the Irrigation Department, Bengal), to the University of Illinois, in engineering , C W O Turner (Wales and the Public Works Department, New Zealand), to Stanford University, in engineering.

Science News a Century Ago

Poinsot and Poisson

Among the journals of a century ago which recorded scientific events were the *Athenæum*, from which the following note is taken It was at a sitting of the Paris Academy of Sciences on May 20 that M Poinsot commenced reading his memoir, a New Theory of the Rotation of Bodies", in which he presented new views Having arrived at these by a direct consideration of the nature of rotation, M Poinsot launched out into praise of the mode of discovery and spoke at the same time in terms rather slightingly of the analytic and algebraic modes of examining a question M Poisson, an academician of the analytic school, took fire at these reflections and came down the next week with refutations M Poinsot rejoined, instancing a mistake made by D'Alembert During the discussion, divers allusions, so the writer said, were made such as in a certain honourable house would have called for the interference of the 'Speaker' Upon the whole, the synthetic method seemed to have had the best of the argument, although M Libri, the Florentine geometer, joined his anger and argument to those of M Poisson

London Mechanics Institution

The tenth anniversary of this institution, now known as Birkbeck College, was held in the theatre of the institution in Southampton Buildings, Chancery Lane, London, on May 22, 1834 Dr Birkbeck presided over an audience which included many distinguished literary and scientific men After some preliminary remarks by Dr Birkbeck and the award of the prizes, five resolutions were passed The third of these was that the manifestation of talent developed within the walls of this institution shown on the present, as on former occasions, is a proof of the wisdom of the plan here first widely called into practice of disseminating useful science through the industrious classes of the community and gives substantial earnest that through the agency of these self ruled and self supported establishments the barbarism of ignorance, with its concomitants, vice and misery, will be more rapidly dispelled and the moral, the intellectual, and the social condition of man be raised to that higher level which becomes his character as a rational and responsible being" By the fifth resolution the meeting offered 'its unalloyed congratulations to Dr Birkbeck on the steady advancement and the present state of this flourishing and useful institution over which he has from its foundation paternally and anxiously presided without deviation, and that the most hearty thanks of this meeting are due, and are hereby presented to that able individual for the powerful assistance given to this institution on this and every occasion"

The Franklin Institute

At the monthly conversation meeting of the Franklin Institute held at Philadelphia on May 22, 1834, Prof Johnson made experiments on the centrifugal force of liquids, in refutation of certain statements made by M Thayer, in a paper read to the French Institute, an outline of which had been given in the *Revue Encyclopedie* of September 1833 The liquids used were oil, water, alcohol and mercury, and the experiments embraced the cases of rotation about the axis of a vessel in which the oil and water were placed, as well as the vibration of the vessel containing alcohol, water and mercury

At the same meeting Dr Jacob Green exhibited an electromagnetic apparatus by Dr Henry for the production of reciprocating motion, by the combined action of electromagnetic currents and of permanent magnets, and Prof A O Bache showed apparatus for the polarisation of light This apparatus had recently been imported for the Friends College at Haverford The polarising effect of the tourmaline was seen by a simple arrangement of two plates of that mineral cut parallel to the axis and fitted with wire rings so as to admit of rotation while the planes remain parallel to each other

The Duke of Sussex's Soirées

His Royal Highness the Duke of Sussex as president of the Royal Society, manifests a liberality and courtesy highly honourable to himself, and entitled to imitation by other noble and eminent persons who are advanced to similar stations by the members of their respective societies Occasionally, during the winter season, his Royal Highness invites some of the leading members of the Royal Society to dine with him at Kensington Palace, and on the same evening receives a large assembly of visitors from 9 to 12 o clock On these occasions many of the first nobility and gentry of the country thereby meet some of the most eminent men of science professors of the fine Arts, and literary characters

The presidents of the Astronomical Society, Mr Baily—of the Geological Mr Greenough are in the habit of having frequent dinner and evening parties of the members of their respective societies and thereby contribute very materially to promote science and a friendly intercourse amongst its lovers and patrons These gentlemen are rarely ever absent from their presidential duties and thus manifest a laudable zeal and a positive attachment to that science over which they are elected as professional guardians

Two of the Duke of Sussex's meetings have taken place since Christmas and two others named on the invitation cards For the purpose of gratifying the company and furnishing matter for conversation, various objects of art science, vertu literature, etc , are placed on the tables and the choice treasures of the library are accessible through the obliging attentions of Mr Pettigrew his Royal Highness's librarian The unrivalled collection of Bibles is a source of great interest to many persons Among other objects exhibited have been a series of marbles of different countries and qualities, on which Mr C H Smith has lectured , a model of a machine for polishing lenses a very curious model of the Great Pyramid of Egypt, made by Mr Davidson , and a series of drawings illustrating the architectural antiquities of different ages and different countries, being part of Mr Britton's extensive series for his lectures ' (*Gentleman's Magazine*, May 1834)

London Horticultural Society and Garden

"The Anniversary Meeting took place, when a report on the affairs of the Society was read, and officers elected It appears that there has been a surplus of income over expenditure for the year ending March 31 1834, of 1574l 18s 7d Out of this sum the Society have paid off two bonds amounting to 920l , leaving the gross amount of the debt at 17,602l 11s 9d , which, there can be no doubt they will soon be able to discharge The Show at the Gardens on May 10 was the best that has yet taken place The first striking object on entering was the Wistaria Consequana, covered with some thousands of bunches of flowers , most of which were expanded to the point of their greatest beauty and but a few so far have begun to drop their corollas ' (*Gardener's Magazine*, May 1834)

Societies and Academies

Pride and Prejudice in Africa

DESPITE the obligations which in common with France and the Union Government of South Africa Great Britain has incurred in accepting the trusteeship of some four millions of Africans under mandate from the League of Nations a rather vague pride in past achievements in suppressing the slave trade and a careless prejudice against any claims of the native races to be more than hewers of wood and drawers of water colour much of such public opinion as is from time to time called into existence by affairs in Kenya Colony and Tshekedi or similar incidents The situation is all the more deplorable in that during recent years there has been available a wealth of material which can assist the intelligent layman to pass accurate judgment on African affairs such as the reports of the East African Commission of 1924 under Mr W G A Ormsby Gore and of the Hilton Young Commission in 1929 Lord Lugard s studies of the principles of administration of backward races and so on

The most disturbing forces in the life of Africa at the present time arise from the insistent demand of the rest of the world for the products of tropical Africa This demand has set in motion economic forces which are producing revolutionary changes in vast areas where European settlement is impossible They are disintegrating the fabric of tribal life and creating problems of administration which cannot be left alone above all in the light of the calamitous experience of South Africa Apart altogether from the new standard of administration to which we are committed in Tanganyika Territory and which has been accepted as the standard of administration elsewhere in our African territories industrial conditions are poising problems which make a policy of *laissez faire* as dangerous from an economic point of view as it is morally indefensible

Of these problems the study of conditions in the copper belt of Northern Rhodesia with particular reference to the effect of the mines upon native society and upon the work of missions carried out in 1932 under the auspices of the Department of Social and Industrial Research of the International Missionary Council* provides many striking illustrations The copper belt of Northern Rhodesia was chosen as the chief field of study because its mines are among the latest that have been opened in Africa and they have been developed with a vigour and on a scale that have attracted a large native working population In addition the position of these mines between those of the Belgian Congo and the Union of South Africa with their widely contrasted labour policies gives Northern Rhodesia an opportunity to profit from the experience of its neighbours Many of the acutest difficulties in Africa to day are unfortunately the direct result of neglect sometimes deliberate of the lessons of history

---

* Modern Industry and the African an Enquiry into the Effect of the Copper Mines of Central Africa upon Native Society and the Work of Christian Missions made under the auspices of the Department of Social and Industrial Research of the International Missionary Council By J Merle Davis Pp xviii+425 (London Macmillan and Co., Ltd 1933) 12s 6d net

This study makes it abundantly plain that the working of the copper mines is raising problems which go far beyond the immediate social and economic problems in the vicinity of the mines The withdrawal of labour from the native areas with a consequent shortage of man power for cultivation of essential food crops is threatening the whole economy of native life quite apart from the disintegrating influence of the new outlook and new needs acquired by natives working on the mines The structure of native society is being knit with our own in ways which it is now well nigh impossible to disentangle

It is of course clear that at the mines themselves problems of social welfare present an important field for scientific study and one in which co operation between the mines missions and Government is highly important Such co operation based on a careful study of the actual conditions might make a contribution to a better understanding between the natives and Europeans to the education of native society and the enrichment of the community at the mines and through it and through the network of native interests created to the foundation of an urban native society

Economic conditions present a particularly strong challenge Co operation of the type just visualised is fully as important in relation to the building of permanent communities round agriculture through the rotation of crops use of fertilisers soil conservation etc in place of the semi nomadic native methods which are inadequate to avert the continual threat of famine Much might be done by co operative methods to supplement the present training and experience of the native employed on the copper belt so as to increase his economic power on returning to rural life Agriculture in Africa to-day in all its aspects —technical social and economic—provides a field in which intensive scientific study is urgently needed and it is a sore reproach to the administration in Northern Rhodesia and elsewhere that funds for demonstration and experimental work under the Department of Agriculture have been cut to the bone

However just when science is affording growing support to the administration in its efforts to develop self government in accordance with native law and custom economic conditions and the impact of modern industry are strengthening the disturbing or opposing forces Discontent with the tribal system and its inadequate adaptation to the industrial revolution in Africa was a prime factor in the unrest which led to the Tshekedi incident An important paper by Dr R S Rattray at the Leicester meeting of the British Association directed attention to some of the doubts and misgivings regarding this system which are arising in spite of its promise for the preservation of the African national genius

The attack on the system of indirect rule comes partly from its tendency in the absence of adequate anthropological knowledge or experience on the part of those administrating it to build up centralised African autocracies out of harmony with African institutions and traditions It comes partly from the growing class of educated tribesmen who can find no place in a system which seems to discount Western education and Western lines of progress This element is being strongly and continuously reinforced by the wage earning class who have similarly been detribalised by their employment at the mines and have equal difficulty in finding a place in tribal society

These factors are shaking the existing system to its foundations There is widespread belief among the educated Africans which was encouraged by the reports of the Phelps Stokes commission that indirect rule and anthropology are veiled attempts to keep the African in his place Without the co operation of the educated native the whole structure of indirect rule must crumble and the fruits of anthropological research must be lost Only a determined attempt to develop an intelligent native leadership and a sound public opinion are likely to save the situation and here once again success will depend on adequate co-operation and harmony between industry missions and Government In each sphere there is need of fuller sympathy depending on accurate knowledge of native religious beliefs and old customs

The absence of that sympathy accounts directly for much native unrest as well as for recent mistakes in administration which have augmented such unrest Unrest is strongly reinforced moreover by the disproportion between the sums collected from natives and Europeans in taxation and the expenditure of those sums on social welfare and educational work among the natives From an industrial point of view the importance f sympathy and understanding of native customs and beliefs is already being recognised but the significant contribution of scientific work in these fields in establishing a relation of mutual confidence and respect is imperfectly apprehended by industry

From whichever aspect we survey them however African problems provide a surpassing field for scientific investigation and endeavour and the report before us indicates yet again some of the more important lines of work—the study of the various problems affecting public health whether in the mines or in the agricultural communities the improvement of the standard and quality of native agriculture both in respect of food and of economic crops provision of adequate transport in regard to the marketing of African produce and the mobility and efficiency of labour and the development of education so as to assist the native whether as a producer or as a wage earner to advance in the scale of civilisation and assimilate such moral controls as will enable him to resist the dangers and yet to utilise the advantages of increasing wealth

Here is a programme in which scientific work must play a decisive part but there is an even more important contribution which science may yet make In a brilliant criticism of the Rhodes lectures of General Smuts Mr J H Oldham has pointed out that just because Africa is only at the beginning of its development it may offer one of the most fruitful fields of experiment in regard to the place of expert knowledge in political affairs What is needed is a far sighted policy directed towards the economic development of the great resources of Africa on scientific lines in the interests of the native inhabitants the immigrant European and Indian communities and the world at large and at the same time promoting the physical intellectual moral and social advance of the African peoples Missions no less than Government and industry must have a clearly defined policy and there is no room in such a policy for prejudice

The new possibilities of service which science has opened up in dealing with the problems of dependencies are as yet largely unappreciated To urge that the scientific outlook and method should become an increasing factor in government is not to advocate the rule of a bureaucracy It offers much greater assurance that the human factors will be fully considered that account will be taken of the prejudices and beliefs of all parties and not merely of those of one section and that an honest attempt will be made to sort out the real cause of unrest The possibilities of mastery which science has given us in problems of government propound moral questions the answers to which depend on our scale of values and the application of scientific thought and method to African problems will in the e[illegible] be justified by the ability of science to keep those who use it loyal to the conceptions of disinterested service implicit in the spirit of science itself

The Complete Guide to Astrophysics

Handbuch der Astrophysik Herausgegeben von G Eberhard A Kohlschutter und H Ludendorff Band 1 *Grundlagen der Astrophysik* Teil 1 Pp xii+564 99 gold marks Band 2 Halfte 1 *Grundlagen der Astrophysik* Teil 2/1 Pp xi+430 69 gold marks Band 2 Hälfte 2 *Grundlagen der Astrophysik* Teil 2/2 Pp vii+431 752 57 20 gold marks Band 3 Halfte 1 *Grundlagen der Astrophysik* Teil 3/1 Pp x+474 77 gold marks Band 3 Halfte 2 *Grundlagen der Astrophysik* Teil 3/2 Pp viii+475–832 62 gold marks Band 4 *Das Sonnensystem* Pp viii+501 78 80 gold marks Band 5 Halfte 1 *Das Sternsystem* Teil 1/1 Pp x+574 99 gold marks Band 5 Halfte 2 *Das Sternsystem* Teil 1/2 Pp x+575–1156+2 plates 99 gold marks Band 6 *Das Sternsystem* Teil 2 Pp ix+474 68 70 gold marks (Berlin Julius Springer 1928–1933)

THE need for such a work of reference as is supplied by the Handbuch der Astrophysik has become growingly obvious as successive volumes have appeared The reviewer can speak from personal experience of its extreme usefulness in the observatory library and of its general completeness within its own scope as a work of reference The articles contained in the different volumes may be divided into three groups—the theoretical the instrumental or optical and the observational It must not however be supposed that there is any rigid division between these groups The articles necessarily and rightly overlap Thus an instrumental article on photometry quite properly has special reference to the astronomical applications and may well trench upon the domain of the article on the luminosities and colours of the stars The fact that the two overlapping articles approach the same subject from two different points of view may lead to slight confusion here and there but is probably more of a help than a hindrance to the student of the subject

The theoretical articles may be subdivided into two sets one of which belongs rather to the domain of pure physics though headed in the direction of astrophysics and to some extent limited to the requirements of the astrophysicist such articles as those on optical theory theoretical photometry radiation the principles of the quantum theory laws in series spectra multiplet spectra and band spectra all come under this head The more astronomical articles of a theoretical type are those on the thermodynamics of stars the theory of pulsating stars and the ionisation of stellar atmospheres In these articles gaps in the existing literature on stellar atmospheres are well filled in up to the date when the articles were written

The optical or instrumental articles include an account of the construction and testing of telescopes and a discussion of the problems of practical spectroscopy Full details are given of the instruments used and of the methods to be employed in astrophysical work in photographic and photoelectric photometry also in visual photometry spectrophotometry and colorimetry Special attention is paid to work on solar radiation The reduction of photographic plates is a subject that one might scarcely expect to find in an astrophysical Handbuch but its presence as a separate article indicates how widely the editors have cast their net

The third group of articles deals with the results of observation and gathers together a great wealth of scattered data often difficult of access They give in general a very readable if at times somewhat uncritical account of the special subjects under discussion Naturally a wide range of topics calls for mention stellar spectroscopy (classification and radial velocities) variable stars novæ binary stars (visual and spectroscopic) solar radiation solar physics eclipses comets and meteors photometry of planets stellar photometry stellar temperatures stellar luminosities and masses nebulæ the Milky Way, stellar clusters and stellar statistics are among the subjects treated in separate articles of very varying length It will give an idea of the general scale of the work to mention that in the article on variable stars 74 pages are devoted to stars of the Mira Ceti class and 41 pages to Cepheids

The articles are written in English or German at the choice of the various authors Half of the thirty three contributors are German but articles have been contributed from eight other countries the whole work may be regarded as one more example of that international co operation which has always been so valuable in the world of astronomy The appearance of successive volumes has extended over a period of five years This is reflected in two ways on one hand where theory has been rapidly developing as in the quantum theory or the study of stellar atmospheres it is almost possible to date the articles by the outlook they represent and different articles may approach the same question from very diverse viewpoints on the other hand where fresh observations have been accumulating as in the study of line contours and intensities there are already obvious gaps in those articles which were published several years ago It is a pity for the sake of their use as sources of reference that the articles are not dated but a supplementary volume is intended and that may remove this difficulty It will be a great help if the supplementary volume could contain a complete subject index for all ten volumes at present it is not as easy as it might be to trace a subject back to the one or two overlapping articles in which it is discussed or to find exactly where a subject is treated on the particular side in which a reader may be for the moment most interested

With regard to the form of publication of the volumes we may note that the printing is clear and very readable this including the numerous valuable tables the text is also very free from misprints Illustrations are lavish and well reproduced—perhaps the article on solar physics is best served in this particular For volumes that are likely to be well used the binding is not as good as it might be and the lettering on the backs is liable to be somewhat easily obliterated

Passing from the general to the particular it is impossible within the limited range of a short review to discuss seriously 36 articles extending over 4 000 pages but it may be possible to give an indication of their character by selecting a few, frankly recognising that they represent a purely personal choice on the part of the reviewer Prof Abetti in his well illustrated article on solar physics discusses solar spectrographic instruments of various types visual photographic and spectroscopic observations of the sun s surface and the deduced results also theories of the constitution of the sun Dr Graff in his discussion of the planets examines the evidence as to their atmospheres rotations spectra and such allied questions as the nature of the zodiacal light Prof H D Curtis in his article on the nebulæ discusses the different types—diffuse planetary and spiral—with the various theories as to their origin and structure—also such closely allied questions as the expanding universe useful bibliographical information is added Under variable stars Prof Ludendorff classifies the various types showing the links between them and gives a full account of the literature and of the many theories put forward especially with regard to the Cepheid variables The subject of pulsating stars is discussed mathematically in a separate article by Prof F A Milne whose article on the thermodynamics of the stars comes naturally alongside one by Prof A Pannekoek on the ionisation in the atmospheres of the stars

Linking these theoretical articles to observational astronomy with due emphasis on the difficulties underlying work in this sphere comes the article by Prof Brill on spectrophotometry A discussion of sources of error in dealing with the continuous spectrum and line intensities makes clear that existing discrepancies between theory and observation may still be in part due to difficulties in the observational side In this connexion one may express the hope that in the supplementary volume some attention will be paid in any additions to the articles on multiplet spectra and band spectra to the astrophysical interest of the subject The articles by Prof Laporte and Dr Wurm respectively though useful and complete partake rather of the nature of textbooks on the subject and are not obviously what might be expected in a volume of primarily astrophysical interest

In conclusion a word of gratitude is due to the editors of the Handbuch for the laborious task that they have undertaken and carried through so successfully They have placed all workers in the subject under a heavy debt and they have gathered together within easy reach much information that may be valuable to those researching in allied fields

An Account of the Genus Meconopsis By George Taylor With Notes on the Cultivation of the Introduced Species by E H M Cox Pp xiii+130+29 plates (London New Flora and Silva Ltd 1934) 20s net

THE Natural History Museum is happy in possessing a band of young field botanists who bid fair to bring botanical science lately overshadowed by the romantic march of the physical sciences once more into high repute Of this band Mr Taylor is not the least *Meconopsis* is one of those select genera dear to horticulturists But for them it might long have languished in darkness unhonoured and unsung British horticulturists have stimulated discovery cultivation and study and Mr Taylor with a wealth of material living and dead before him collected primarily in the interests of horticulture has presented them with a new classification and brought our knowledge of the genus up to date

It is however botanists rather than horticulturists who will be interested in what Mr Taylor has to say The author has a wide acquaintance with his subject and is both lucid and provocative he is not the worse botanist for that Old mistakes are resolved tangles untangled new ideas infused It would be no compliment to say that all taxonomists will accept his rearrangement of the genus but his opponents will need to be well equipped before joining issue with him

Mr Taylor takes up the position that species are distinguished by fixed morphological characters not connected by intermediate forms conversely if there are intermediate forms they embrace one (Linnæan) species no matter how extreme the divergence He has applied this principle ruthlessly to *Meconopsis* other taxonomists have not applied it to for example *Rhododendron* There seems to be no relationship between the age of a genus and its degree of stabilisation and *Meconopsis* is not more polymorphic than *Rhododendron* Stabilisation is probably more a function of space than of time Cytology may help in the delimitation of species but as Bruun has insisted in his Cytological Studies in Primula (Uppsala 1931) chromosome differences constitute only *one* character comparable to a morphological character though perhaps more fundamental Nevertheless the results are sometimes surprisingly at variance with visible differentiation for example in section

Sikkimensis of the genus *Primula* Mr Taylor faces the difficulty boldly, and takes his own line He may be right in attaching more importance to stylar than to epidermal structures, though both are probably artificial in the sense that we cannot link them to any function, or trace their evolution Indeed the author expressly denies any relationship between his subgenus *Discogyne* and *Papaver* Then, when he comes to *Meconopsis integrifolia*, he waxes a little impatient over the synonymy, based on styles, and helps the lame dogs over theirs with a flying leap Nor is he quite consistent, since he advances the same argument for unity here that he advocates for separation between *M venusta* and *M impedita* It is surprising, too to find him upholding, even provisionally, *M argemonantha* on the woefully imperfect material available The fate of *M Baileyi* should have warned him

No really satisfactory system of representing distribution has yet been devised To enclose all recorded areas for a taxonomic unit has its uses, but the method is apt to obscure more than it reveals Some adaptation of the layer system might be employed Mr Taylor gives us several maps, but we are left with an empty feeling that they convey no more than meets the eye We should have preferred distribution maps of the more comprehensive species, such as *M horridula* and *M impedita*, especially in combination with larger taxonomic units The statement (p 94) that "all forms [of *M horridula*] may be found growing in association in the field" is surprising, though its correct interpretation depends upon the scope of "in association" The reviewer's experience is that *all* varieties, even colour varieties, of *Meconopsis* definitely tend to segregate Again, the statement (p 33) on the authority of a collector, that *M superba* grows "above the snow line" is equally surprising—if true

Mr Taylor does not mention latex, though the colour of this is sometimes a useful diagnostic character Nor does he mention that the seeds of *M betonicifolia* are eaten by the natives in lieu of *Papaver somniferum*, and so may be assumed to possess narcotic properties

But the mantle of Sir David Prain, whose last revision of the genus was published nearly twenty years ago, has fallen on worthy shoulders At the prohibitive price, the format might have been better Some of the photographs are excellent, we should have preferred some line drawings of capsules, in the text, for others

Social Values

The Conflict of Values By J R Bellerby (Published by Education Services) Pp xi+204 (London Richard Clay and Sons, Ltd, 1933) 6s net

AN encouraging sign of the times is the clearer recognition of the need for experiment in economics and sociology The difficulties in the way of practical work in this field are of course sufficiently obvious, but they are surely not insuperable, and the need for overcoming them was never greater than now

As Mr Bellerby shows in his new book, the first step for a nation as for an individual is to have some definite aim and purpose, an architect's plan an ideal State shining as a star ahead, never actually attainable, but inspiring our best efforts in the search for real values This would appear to be the first law both in individual and social psychology Mr Bellerby endeavours in a philosophical discussion, somewhat after the Platonic manner, to discover these values, combine them into a complex 'web of purpose', and relate them to an economic or industrial structure leading as nearly as possible in the direction of the ideal state He brings to his task a highly interesting and attractive style, original and courageous thought, and above all a keen sense of practical difficulties as illustrated by actual test and experiment

The book is a sequel to a previous work entitled "A Contributive Society", and, in the author's own words, is ' the logical completion of that work, giving point to its main theme by describing the life values, or the scheme of values, which may be achieved through contribution"

This first chapter marks the end of the first phase of theory, after which the experiment is described, from which useful criticisms have been drawn The attempt is made to illustrate a 'contributive' society, in contrast apparently with Mr Tawney's 'acquisitive' society Inspired by a new estimate of life values, which, however, in themselves are not new since they go back to Plato and Christ, the members of this social group endeavour to contribute a maximum both of service and worldly goods or money to the common fund, on the principle of the 'average wage' The group is established on a purely voluntary basis, without compulsion of any sort, and the life values which are re stated in relation to modern economics are those concerned with beauty, truth (or knowledge), and love For the individual the aim is to develop personality to the utmost, and in doing this in the right way the greatest advance will be made towards attaining the ideal State or community

This question of values in social philosophy has exercised the greatest minds in all ages, and has led to visions of many Utopias, those of Plato, More, Morris, Bacon, and others, most of them being here briefly outlined and discussed by Mr Bellerby, including a note on the inner meaning and implications of progress, and the contrasts between the Western mind of breathless activity and the Oriental mind of calm meditation The theory of social evolution is apparently accepted by the author, but this somewhat complicates matters, tending as it must do to a fatalistic outlook, especially if one goes so far as Keller and Sumner (in ' Societal Evolution"), wherein there is not necessarily any progress, and human destiny is determined by the operation of blind, impersonal, yet invincible forces

The 'web of purpose', and the setting up of an economic system must before all things be purposive, and contribute to the development of personality "Its processes must be such as to challenge and demand character, and its product must aid men to strong growth" This view of one of the aims of industry has already been outlined in the columns of NATURE by the present reviewer, as also was another important point, referred to by Mr Bellerby as the central problem of his book This is the question of what best constitutes the 'web of purpose' and ideal to be aimed at Is it the militaristic ideal of the Vikings, the bustling activity and obsession for business of the western nations of Europe, the meditative philosophy of the Oriental, or religious piety, or scientific attainment ? The answer given long ago, and now given again by Mr Bellerby in almost the same words, is that the ideal State, embodying the ideal industrial system, so far as this is conceivable, will not be one fixed or static and stereotyped system, based on one single ideal, like that of large scale mechanised industry for example (if this is really an ideal) Certainly it does seem that this is the inevitable outcome of present tendencies, but these tendencies are not necessarily right or inevitable, especially when viewed in the light of a philosophical analysis of values

Mr Bellerby particularly emphasises the need, as has already been done before in these columns, for elasticity and variety, for both breadth and depth, in the contributive society, so that not one ideal only but probably many ideals may find inspiration and scope So far as the industrial structure is concerned, it was long ago pointed out by some of us that room should be found for many different forms of industry, both large scale and small, both mechanised and handicraft, competitive and co operative, individualistic and communal That there may be incompatibility and even conflict between the various ideals is realised by Mr Bellerby in the very title of his book, but this need not deter the far sighted statesman and an intelligent and educated people from attempting a nice balance between all the various elements which should go to make up a great industrial and agricultural nation

Short Reviews

Muller Pouillets Lehrbuch der Physik Elfte Auflage Herausgegeben von A Eucken, O Lummer und E Waetzmann In 5 Banden Band 4 *Elektrizität und Magnetismus* Teil 4 *Elektrische Eigenschaften der Metalle und Elektrolyte, magnetische Eigenschaften der Materie* Herausgegeben von Arnold Eucken Pp xx + 906 (Braunschweig Friedr Vieweg und Sohn A G, 1934) 62 gold marks

THERE is no doubt that this final portion of the fourth volume of the eleventh edition of such a well-known treatise on physics is bound to be of interest to all who teach modern physics or who are interested in research on the conduction of electricity by solids and liquids The book gives an excellent treatment of the experimental aspects of the electrical properties of metals, including an important section on thermo-electric effects It also includes an adequate discussion of thermionic phenomena, and a very satisfactory statement of modern statistical and kinetic theory of the metallic state is contributed by Nordheim

Coehn of Göttingen is responsible for the account of electrolytic processes, including an important section on the modern theory of strong electrolytes, while Jost of Hanover appends an account of the electrical conductivity of non-metallic crystals O v Auwers, whose recent work on hysteresis cycles of the perminvars aroused much interest, gives a very concise treatment of magnetic phenomena, and a survey of the quantum theory of magnetism, by Nordheim, completes a very fine work

It is almost unnecessary to add that the standard of the production is in all respects equal to that of the first three parts of the volume

Meteorology for Masters and Mates By Charles H Brown Seventh edition Pp ix+234 (Glasgow Brown Son and Ferguson Ltd 1933) 7s 6d net

THE object of this book appears to be mainly to assist those taking the master s and mate s examination to answer questions in meteorology which demand a greater knowledge than seems to be required according to regulations It should however also help to stimulate interest in the subject and assist in producing a generation of seamen able to take full advantage of the help in navigation that can be obtained from the exchange by wireless of weather information between ships at sea and shore stations The author goes more into the physical causes underlying meteorological phenomena than he did in the earlier editions of the same work From the point of view of the examinee the arrangement of the subject matter appears excellent the syllabus for the first mate s as well as for the master s examination is given at the beginning and examination papers are set at the end with references to the parts of the work dealing with the subject matter of each question

Under Velocity of Gales (p 86) it is stated that It is to be understood that the direction and force of the wind depends on the part of the depression that the observer is situated in but that the speed of a gale is really the rate of travel of the system which has the implication that a gale never occurs in a stationary depression On the same page there is the further statement that the force and frequency of the squalls of wind depend not on the gradient alone but also on the distance from the centre of low pressure It would be interesting to know what evidence there is in support of this statement E V N

Santiago de los Caballeros de Guatemala By Dorothy H Popenoe Pp xvi+74+7 plates (Cambridge Mass Harvard University Press London Oxford University Press 1933) 6s 6d net

THE Spanish city well described and illustrated in this volume was begun towards the middle of the sixteenth century as the third capital of the colony of Guatemala after the second one Almolonga built by Alvarado had been destroyed by earthquake Much of the city known to day as Antigua Guatemala still stands but it lies in a volcanic area and suffered repeated earthquake shocks until in 1773 it was so badly devastated that Spain ordered its abandonment and the removal of the capital to a new site the modern Nueva Guatemala Mrs Popenoe had made a wide study of Central American archæology and written this book shortly before her untimely death She has succeeded in reconstructing the life of the city and much of the beautiful architecture of the early Renaissance which characterised the first buildings The work is based on old documentary records

Kohlensäure und Kalk Einführung in das Verständnis ihres Verhaltens in den Binnengewässern Von Prof Dr Julius Pia (Die Binnengewässer Einzeldarstellungen aus der Limnologie und ihren Nachbargebieten herausgegeben von Prof Dr August Thienemann Band 13) Pp vii+183+3 plates (Stuttgart E Schweizerbart sche Verlagsbuchhandlung (Erwin Nägele) G m b H 1933) 21 gold marks

THE present volume of Die Binnengewässer is a treatise on carbonic acid and chalk in fresh waters It is a comprehensive work and like all the previous parts covers much ground and the subject is considered from many different aspects The three parts into which it is divided deal respectively with chemical constants and theories of solubility in organic and organic precipitation and the most important chalk deposits Compared with the condition in the sea the part played by living organisms in connexion with the precipitation of chalk is small the various chemical and physical factors are much more important in fresh waters The research of the various specialists in these subjects is fully described and there is a bibliography of 26 pages making this volume a most satisfactory work of reference

La France méditerranéenne Par Prof Jules Sion (Collection Armand Colin Section de géographie No 164) Pp 222 (Paris Armand Colin 1934) 10 50 francs

PROBABLY no region of France has more distinctive physical conditions and human characteristics than the Mediterranean border The difficulty in discussing this region lies in fixing its limits Prof Sion has wisely confined his attention to the plains the delta of the Rhone and the coastal ranges of hills After briefly explaining the structure he goes on to discuss human relationships historical economic and demographic tracing with a sure knowledge the reasons for the various changes that the region has undergone of which none is more interesting than the decline of wheat and the development of viticulture and the rise of the various seaports No student of geography can afford to miss this important though small work on the geography of France R N R B

Plant Life Through the Ages a Geological and Botanical Retrospect By Prof A C Seward Second edition Pp xxi+603 (Cambridge At the University Press 1933) 30s net

IT is unnecessary to emphasise the authoritative nature of this geological and botanical retrospect the name of the author who is professor of botany in the University of Cambridge carries sufficient guarantee The fact that within two years a second edition of a specialised work has been called for speaks well for its success The first edition was reviewed at length in NATURE of October 3 1931, p 559 A few alterations and corrections have been made and more references added in the present edition

Twenty One Years of Fruit Research at East Malling

THE Fruit Research Station at East Malling, in the heart of the Kent fruit area, which was established in 1913, at the request and with the active and continued assistance of fruit growers, celebrates its coming of age at the annual meeting of its supporters on May 24 The occasion is being graced by the presence of His Royal Highness the Duke of York, who has consented to honour the Station by visiting its plantations and laboratories on that date when the Institute's subscribing members, now numbering 1,000 will have their annual opportunity of making a closer acquaintance with the results of the experimental work, special demonstrations of which will be staged

A prime essential for the successful prosecution of research on fruit plants is continuity of policy If more than fragmentary information is to be obtained experiments must cover a reasonable proportion of the useful life of the subject, so that an investigation even of strawberries may last four or five seasons, whilst the full value of trials of tree fruits may not be obtained in less than twenty years

Since 1913, in spite of the necessary restriction of its activities during the War years, the Station by adherence to a clear cut programme of long distance research in the field and in the laboratory, has obtained results of fundamental importance to fruit growers The annual total of 2 000 interested inquirers who visit the Station is an indication of the confidence placed in its work by the industry, which recognises that the best fruit must be grown before the best marketing methods can be applied

Important contributions have been made to the practice of the culture of small fruits such as black currants and raspberries, first by systematic botanical studies of varieties, which made possible accurate identification and consequently the accumulation and maintenance of races and strains true to type Only when this had been effected was it possible to begin field trials to determine the cropping capacity, manurial requirements, disease resistance and market value of the multitude of varieties available in commerce Such investigations, coupled with the elaboration of methods of control of pests and diseases, have been the main factor in lifting black currant culture from a haphazard gamble to its present condition of an organised system of operations which can be undertaken with a reasonable certainty of success

Similar methods, linked up with the evolution of a scheme of nursery hygiene, have been applied to raspberry growing, and a large measure of success has already been obtained, whilst problems of the propagation and control of diseases and pests of the strawberry, loganberry and blackberry are under investigation

Fruits such as apples, pears, plums and cherries, the trees of which are budded or grafted on root systems other than their own, present problems similar to those of the small fruits, but, in addition, further complications are introduced by the presence of the foreign root system The first step was the collection of examples of these rootstocks from a wide range of commercial sources, and after meticulous botanical examination it was possible to construct a very necessary system of classification for identification purposes and to avoid future confusion The next stage was the multiplication of the different rootstock types and for this purpose vegetative methods were resorted to in order to preserve to each its own genetic constitution This process alone involved a prolonged intensive investigation since many varieties did not propagate easily and special methods had to be evolved to apply to different cases Trials have been made with hardwood and softwood cuttings, root cuttings layers and stools, and thus was found the most suitable method for each variety The next process was the raising of series of trees of commercial scion varieties budded or grafted on each type of rootstock, and these were then planted out grown under a recognised commercial system of culture and intensive records of individual tree performance were taken over several years The records include annual measurements of the total length of new shoots the girth of the trunk, the height and spread of the branches, leaf area the number of blossom trusses formed and the number size, colour and quality of fruits

In parallel with field trials of this type, experiments have been carried out in which similar trees are subjected to different degrees of winter stem pruning, the effect on subsequent performance being measured by a series of routine records as in the rootstock trials

Manurial investigations have been conducted, both in the field and in pot culture, and valuable information relative to this subject has also been obtained by work on the spatial distribution and time of growth of roots A number of trees up to ten years old on different soils have been excavated piecemeal and then reconstructed, giving a picture of the spread and depth of the roots to which manurial substances have to be supplied The time and rate of root growth are determined by direct measurement of growing roots through glass windows in the sides of underground observation posts

These and other converging lines of research have now made it possible to classify the rootstocks on the basis of the influence which they exert on the scion, and the trees growing in the plantations of the institute, each coupled with its own particular record of past performance, demonstrate the fundamental importance of using standardised rootstocks, chosen with full regard for their potentialitites, which are now known with considerable accuracy

It has of course long been known vaguely that the rootstock has some influence on the performance of a tree but the accumulated results of the Station s experiments have shown just what this influence may achieve and how advantage may be taken of it though it is not yet clear what physiological and chemical mechanism is involved in the translation of rootstock potentialities into scion performance It is however now certain that choice of rootstock may mean the difference between the economic success and failure of a plantation since such factors as the vigour and disease resistance of the tree the age at which fruit production begins the amount of crop and the size colour and quality of the fruit may all be affected by the rootstock

Some control of these factors may of course be achieved by such cultural treatments as pruning and manuring but since tree fruit plantations are planned in relation to a future of 30–50 years the importance of obtaining control of the trees by selecting at the outset the correct rootstock in relation to its purpose need scarcely be emphasised The extent of this control is such that it is now possible by rootstock selection to choose in advance whether a tree shall become a dwarf bush for the garden or a large standard with a spread of 40 ft and in fact to produce at will trees suitable each for its particular purpose

The natural corollary of these investigations was not only to make them known to the fruit growing industry but also to make available the material with the aid of which the principles could be applied Consequently in order to ensure that growers and nurserymen shall be able to procure in quantity suitable rootstocks and desirable and healthy varieties of small fruits all true to type the Station has established a considerable acreage of nurseries where material is raised and distributed through commercial sources The number of plants thus made available now amounts to 250 000 annually The area now under experiments amounts to 130 acres and in the course of the investigations problems have arisen which have necessitated co operation of pomologists physiologists mycologists bacteriologists entomologists statisticians and chemists their publications appear in the Station s Annual Reports and in biological journals chiefly the *Journal of Pomology and Horticultural Science*

The Imperial Bureau of Fruit Production founded in 1929 is housed at the Station and acts as a clearing house of information concerning research on fruit plants which is made available through *Horticultural Abstracts*

Canadian Water Power Developments during 1933

By Dr Brysson Cunningham

THE recent issue by the Dominion Water Power and Hydrometric Bureau of the Canadian Department of the Interior of two reports relating to hydro electric developments during the year 1933 enables a fresh survey to be made of the remarkable progress which continues to be achieved in the Dominion in the exploitation of its natural water power resources

It was scarcely to be expected that the rate of development which from 1924 until the end of 1932 was fairly constant at the high figure of nearly 440 000 additional horse power per annum could be maintained during the present period of economic depression In the circumstances it is satisfactory to record that the net increase during 1933 was no less than 270 210 horse power bringing (with a previously untabled item of 16 600 horse power in 1932) the total development at the beginning of this year up to 7 332 070 It is conservatively estimated that this represents a capital investment of 1 675 000 000 dollars and that it is capable of effecting a saving of about 36 000 000 tons of coal per annum The actual saving for the year 1933 is computed at 14 775 000 tons As projects require several years to materialise the annual increment of power is of course mainly due to installations the inception of which dates back a corresponding period During 1934 and thereafter there will be further increments on the completion of undertakings now under way but from the point of view of the maintenance of the rate of progress it is significant and unfortunate that no undertakings of magnitude were initiated during 1933

The distribution of the present realised total of 7 332 070 horse power among the various provinces of the Dominion is shown in the accompanying table which also exhibits a statement of the estimated total power available It would not be correct however to deduct the realised horse power in column 4 from either of the totals of available power in columns 2 and 3 for the purpose of arriving at the balance still awaiting development because experience in the matter of turbine

AVAILABLE AND DEVELOPED WATER POWER IN CANADA

installation demonstrates the realisation of an excess of some 30 per cent over the ordinary six months' flow power On this basis, it is a legitimate conclusion that the recorded water power resources of the Dominion will permit of a turbine installation of about 43,700,000 horse power, of which the present realised total is rather less than 17 per cent Even so, the per capita development for the Dominion, namely, 686 horse power per 1,000 of the population, places Canada in an outstanding position among countries of the world using water power

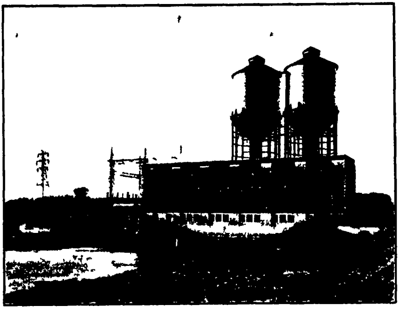

FIG 1 Masson Development Lievre River Quebec, 136 000 h p of the MacLaren Quebec Power Company By courtesy of the Dominion Water Power and Hydrometric Bureau Ottawa

Of the 270 210 horse power brought into operation during 1933, rather more than a moiety (136,000 horse power) is due to the completion of the Masson Development of the MacLaren Quebec Company, situated at the mouth of the Lievre River in Quebec Province, of which a view is given in Fig 1 It comprises four turbine units, each of 34,000 horse power and has a dam and intake 1,050 ft long with a tunnel 6,060 ft long leading to the power house There is an effective head of 185 ft

Another important enterprise, now in hand, is the Canyon Development on the Lower Abitibi River in Ontario, which has been acquired by, the Provincial Government and its operation placed in the hands of the Hydro-electric Power Commission of Ontario Ultimately, the installation will comprise five turbine units of 66,000 horse power each Two of these are complete and in operation, the first having been put into commission in May 1933 and the second in August last A cable line at a voltage of 132,000 transmits current from the Canyon to the Sudbury mining district, 246 miles distant Under an agreement recently concluded between the Hydro electric Power Commission and the Canadian Northern Power Corporation, current from the Canyon will be an important factor in mining development in Northern Ontario

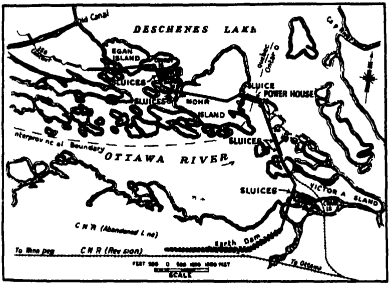

FIG 2. Site plan of the Chats Falls Development

The Beauharnois installation, described in NATURE of June 3, 1933, continues to expand During 1933, contracts were placed for the balance of the equipment (turbines, generators, transformers and switching equipment) necessary to produce the full 500,000 horse power development, and this is expected to be realised in 1936 The present capacity is 133,000 horse power, exclusive of that required for constructional purposes

Although not coming precisely within the limits of the period under review, the Chats Falls Development[1], completed in September 1932, is an undertaking the magnitude of which merits some notice, and, moreover, apart from its outstanding capacity of nearly a quarter of a million horse power, it is the first major power development in the inter-provincial section of the Ottawa River which constitutes a complete exploitation of the whole flow at any site The Ottawa River is the boundary between the Provinces of Ontario and Quebec for a length of 300 miles from Lake Timiskaming to Carillon, a point 25 miles from the junction with the St Lawrence Favourably for the important pulp and paper factories established along its banks, it affords a number of valuable sites for hydro electric power development such as those at Quinze (40,000 horse power), Bryson (25,000 horse power) and Ottawa As will be seen in the plan of the locality (Fig 2) the portion of the river developed at Chats Falls lies between Chats Lake and Lake Deschenes These lakes are really broadened expanses of the river and they have areas of 27 and 36 square miles respectively Uniting them is a channel about 3 miles in length, in which there is a natural fall of about 50 ft, 38 ft of which are in the falls proper at the lower end of the channel and the remainder in the rapids above the falls The rapids and the falls are separated by a sheet of water, one square mile in area, known as the Fishery Pool, and this forms the forebay of the development From records taken over a period of seventeen years, it has been ascertained that the mean flow at Chats Falls is 45,000 cusecs, with a dependable minimum of 22,000 cusecs, which by the enlargement of certain storage facilities on the main stream and its tributaries is susceptible of an increase to 28,000 cusecs

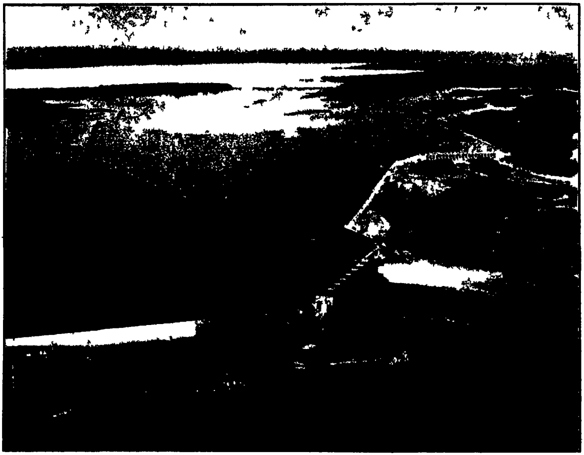

FIG 3 Chats Falls Development 224 000 h p of the Hydro-Electric Power Commission of Ontario and the Ottawa Valley Power Company
By courtesy of the Chats Falls Engineering Board

The present hydraulic installation consists of eight turbines each with a rated capacity of 28,000 horse power under a head of 53 ft and at a speed of 125 rev per minute The operating head varies from 38 ft at times of very high river flow to 58 ft at low flows The photographic view reproduced in Fig 3 which has been courteously supplied by Dr Hogg, chairman of the Chats Falls Engineering Board, shows the power house and forebay with part of the adjacent constructional works, the latter being more completely indicated on the plan (Fig 2) To the left of the power house (in the photograph), on the Ontario shore there are, in turn, a gravity dam some 1,200 ft in length, 32 sluices, known as the Ragged Chute sluices, each with a clear opening of 18 ft, a gravity dam, 1,350 ft long the Victoria sluices, 10 in number, also with 18 ft openings, and a further gravity dam of 1,450 ft length Beyond this, there is a low earthen dyke, or embankment, parallel with the river edge, extending for nearly a mile upstream On account of these works, a section of the Canadian Railway, two miles in length, had to be re-laid farther inshore On the Quebec, or western side, immediately adjacent to the power house are 4 sluices, each 40 ft in width, and a log slide , then a gravity dam, 2,000 ft long , the 10 Wolverine sluices , another dam, 650 ft long , 22 Merrill Island sluices and, finally, a dam, 2,600 ft long, terminating in a number of short disconnected lengths closing low-lying areas Alongside the power house, in the foreground of Fig 3, can be seen the transformer station, consisting of 13 single phase transformers, 13 2 kv to 220 kv , while 800 ft farther along is the 220 kv switching station occupying an area of about 300 ft by 360 ft

Not the least important feature of hydro electrical exploitation on a national or provincial scale is the regulation of water supplies, and in this connexion the work of the Quebec Streams Commission is worthy of notice The Commission continues to maintain with every success the desired regulation of flow on all the controlled rivers through its extensive system of storage reservoirs in various parts of the province It controls seventeen reservoirs, five of which are on the St Maurice River two on the St François River, two on the Gatineau River, one at Lake Kenogami for the Sable and Chicoutimi Rivers , three on the North River (Lakes Masson, Long and Bedini) , two on the St Anne de Beaupré River (Lakes Brulé and Savane) , one on Mitis River and one on Rivière du Lievre The Commission has also proceeded with the further investigation of storage problems on the Upper Ottawa River, including Jourdan Lake Numerous lakes have been examined to determine whether they are to be considered as navigable waters, and river profiles have been taken Studies of ice formation have been made and also sundry investigations of back water and drainage, besides the execution of bank protection work

World Climate during the Quaternary Period

AT the Royal Meteorological Society on May 16 Dr G C Simpson read an important paper on his theory of the climatic variations during the Quaternary Ice Age, with especial reference to its geological implications Briefly, the theory states that the effect of an increase in the solar radiation intercepted by the earth is a relatively small increase in the earth's temperature, but a large increase in the evaporation, cloudiness and precipitation In high latitudes or on high mountains, where the precipitation is mainly in the form of snow, the first result is an extension of the ice sheets and glaciers, but as the radiation increases still further, the rise of temperature becomes great enough to melt away the ice If the solar radiation, starting from a minimum, goes through two complete cycles, the climatic succession would be cold dry climate , glacial , warm wet interglacial , glacial , cold dry interglacial , glacial , warm wet interglacial , glacial , cold dry climate Hence there would be four glacial periods separated by three interglacials, of which only the first and third would actually be warm In low latitudes, on the other hand, the two cycles of radiation would be represented only by two pluvial periods separated by an interpluvial, the maximum of each pluvial coinciding with a warm wet interglacial

The physical basis of the theory offers no difficulty, requiring only that the earth shall fluctuate in the unstable zone between insufficient snowfall and too great heat The real test is whether the theory fits the geological facts, and in his latest paper Dr Simpson arrays an impressive mass of evidence that the fit is very good indeed Two primary difficulties are first attacked , the centre of glaciation in the northern hemisphere was not the north pole, but lay somewhere in Greenland, while careful analysis by Penck and Brückner has shown that, in the Alps, glaciation was not due to increased snowfall but to decreased temperature Both these difficulties are explained by the geographical fact that the North Atlantic is open to the Arctic, while the North Pacific is not During the oncoming of a glacial period there was a great accumulation of floating ice in the Arctic Ocean, and the only outlet through which this could escape led into the Atlantic, which was covered by ice floes down to comparatively low latitudes, while the Pacific was ice free This floating ice greatly lowered the temperature of eastern North America and still more of western Europe, and led to the great extension of glaciation in countries bordering on the Atlantic In the early stages of the Quaternary, however, communication between the Arctic and Atlantic was more or less interrupted by a bar between Greenland and Norway or Scotland , until this bar was submerged, glaciation was unable to develop over the British Isles

In another respect the classical work of Penck and Brückner in the Alps fits the theory very closely, giving exactly the required sequence of four glacial periods and three interglacials, of which the second was known to be very long compared with the third, while the latter was exceedingly wet and warm The theory is supported also by recent discoveries in tropical Africa of two great pluvial periods separated by a very dry interpluvial Archæologically, the third interglacial is dated in Europe by the Acheulean, which is everywhere associated with a warm fauna From the geological record, Dr Simpson estimates that at the maximum of the solar radiation the temperature was between 5° C and 10° C higher than at present and the cloud amount about two tenths greater from these data he calculated that the sun is a variable star with a range of 40 per cent in the intensity of its radiation

Since the chief purpose of the paper was the array of geological evidence in support of the theory, the discussion was mainly carried on by the geologists The present writer gained the impression that the latter accepted the general implications of the theory but found considerable difficulty in agreeing to the details On one point, however there was general agreement the explanation of the discrepancy between the centre of glaciation and the present north pole by purely geographical reasoning was welcomed as a relief from the difficult assumption of a shift of the poles

The difficulties of detail are threefold In the first place Penck and Brückner s simple scheme of four major glaciations cannot be applied directly to countries outside the Alps In the British Isles for example the succession was much more complicated than that suggested in Dr Simpson's scheme, and even the number of major glaciations has not yet been determined The second difficulty concerns the place in the scheme of the archæological stages Some competent authorities place the Acheulean not in the Riss Würm interglacial but in the Mindel-Riss, which according to the theory was cold and dry Even the climate in which Acheulean man lived has not been surely determined for the interglacial which contains Acheulean implements also includes a loess Allied to this is the difficulty that the Great Chalky Boulder Clay has features which show that the end of that particular glaciation was dry, though by Dr Simpson's scheme it leads up to a wet warm interglacial Finally, one of the fossils used most definitely as an index of a warm climate—*Corbicula fluminalis*—has recently been found associated with a marine cold fauna, and its climatic value is open to doubt Dr Simpson was not worried by these objections maintaining that if his theory is correct he had given geologists a useful means of aligning new discoveries, while existing discrepancies would gradually be cleared up

One interesting point brought out in the discussion was that no difficulty exists from the astronomical point of view in the sun being a variable star A range of 40 per cent means very little in terms of stellar magnitude, and is unimportant compared with some known variations

Obituary

PROF W H WELCH

THE death of Prof William Henry Welch of Baltimore on April 30 at the age of eighty four years removes from the scientific world a man who enjoyed an international reputation as a reformer of medical education sanitarian pathologist and bacteriologist

Shortly after obtaining his medical degree at Yale, Welch spent two years in Europe, where he studied normal histology pathology, physiological chemistry and practical medicine at Strasbourg, Leipzig Breslau and Vienna under the leading teachers of that day, visited various Paris hospitals and attended Lister s lectures at King s College Hospital London He was thus fully equipped with the latest and best medical teaching on his return to New York in the spring of 1878, where he was soon appointed lecturer on pathology at Bellevue Hospital Medical College

In 1884 Welch was made professor of pathology at Johns Hopkins University and pathologist to the Johns Hopkins Hospital Before entering on his new office, he made another journey to Europe, where he studied bacteriology and hygiene under von Pettenkofer, von Flügge and Koch On his return he played an important part in the development of the Johns Hopkins Hospital, and was largely responsible for the election of the other three original members of the staff, namely, Osler, the physician, Halsted, the surgeon, and Kelly, the gynæcologist, who figure with him in Sargent s well known picture From 1893 until 1898 he was dean of the Johns Hopkins Medical School, being succeeded by Osler In 1916 he was appointed the first director of the new School of Hygiene and Public Health at Baltimore and held this post until 1926, when he became professor of the history of medicine in the Johns Hopkins University

Welch's work may be summed up under the headings of sanitation, pathology, bacteriology and medical education As president of the Maryland State Board of Health—an office which he held for twenty four years—he played an important part in converting Baltimore, which had hitherto been a focus of typhoid fever, into a healthy city His advice on sanitary matters was often sought by presidents of the United States and other public authorities, and it was due to him that a Yellow Fever Commission was created, which led to the discovery of the rôle of the mosquito in the spread of the disease He was the author of numerous important articles on pathology, the best known being those on thrombosis and embolism, which were published in 1899 in Allbutt's "System of Medicine" In 1892 he described the *Staphylococcus epidermidis albus* and the *Bacillus aerogenes capsulatus*, the cause of gas gangrene, commonly known as the Welch bacillus.

As medical educationist, Welch is to be credited with having introduced modern methods into the medical schools of the United States and to have trained a large number of pupils, jocularly described as 'Welch rabbits', who afterwards attained a high distinction in the world of medical science

MR H. G. MILLER

AGRICULTURISTS all over Great Britain will hear with deep regret of the death of Henry G. Miller, son of Dr. G. W. Miller, of Dundee, and until lately manager of the experimental farms at Rothamsted and Woburn.

Miller was born in Dundee in 1903 and was in the first instance intended for an engineering career; he entered on the engineering course at the University of Glasgow for this purpose, but his desire had always been towards agriculture and he soon transferred to the agricultural side, and afterwards to the University of Edinburgh. At both places he achieved remarkable success. He was then appointed to an Empire Cotton Growing Corporation scholarship and proceeded to the University of Cambridge and afterwards to the Imperial College, Trinidad, where he studied tropical agriculture and especially cotton growing.

Finding that tropical conditions did not suit him, Miller returned to Great Britain and was appointed farm manager at Boghall, the experimental farm of the Edinburgh and East of Scotland Agricultural College. His work here attracted attention from discerning observers and when the farm managership of Rothamsted became vacant in 1927 he was appointed to it.

Two important tasks were entrusted to Miller at Rothamsted. One was to complete the programme of converting a wholly arable farm without animals into a mixed grass and arable farm carrying a considerable head of livestock. This was done with great energy and efficiency and with a minimum of disturbance of the experimental work. The other task was to deal with the cultivation problems associated with the new methods of field experimentation designed in the Statistical Department at Rothamsted for the purpose of giving an estimate of the error of the experiment, a quantity which agricultural experiments had usually ignored in the past. In collaboration with his colleagues at Rothamsted, methods were worked out which satisfied the requirements both of the cultivator and the statistician.

Miller's personal bent was towards experiments on sheep, and several of these were begun at Rothamsted and will be continued. Perhaps the most interesting was the selection of a number of four-teated ewes and rams from four teated mothers, on the basis of which a little flock is being built up to see whether this character is advantageous to a ewe suckling twins.

Miller's death is a great loss to agriculture as he was a man of undoubted promise. He combined to an exceptional degree the qualities of hard work, enthusiasm and genius for agriculture, and had he lived he would have been marked out for a brilliant career.

News and Views

Lieut.-Col. S. P. James, F.R.S.

THE Darling Medal and Prize was founded by the Health Section of the League of Nations in memory of that great malariologist, Dr. S. T. Darling, who met his death as the result of a motor accident in the Lebanon Mountains outside Beirut when carrying out malaria inspection work for the League. The choice of Lieut.-Col. S. P. James as the first recipient of this award is a most appropriate one, for malaria and the problems associated with it have occupied the foremost place in his mind since he first joined the Indian Medical Service in 1896. In India he carried out important pioneer work on the anopheles mosquitoes and their classification, and laid the foundations of the subsequent malaria work which has been accomplished in that country. He pursued other lines of research, and, independently of Low but a little later, was able to demonstrate that the embryos of *Filaria bancrofti* in their development in the mosquito pass ultimately into the proboscis of the insect, so that there is every probability that infection occurs when the mosquito feed. On his retirement from the Indian Medical Service in 1918, after war service in Mesopotamia, James joined the Local Government Board, now the Ministry of Health, as adviser in tropical diseases. There he was instrumental in organising and developing the malaria treatment of general paralysis in mental hospitals and asylums.

THE opportunity this gave of studying malaria under carefully controlled conditions was fully realised by Col. James, and, as a result, there was established at the Horton Mental Hospital the now well known laboratory, which has been the means of bringing to light a whole array of new and important facts regarding the biology of the various malarial parasites, including the comparatively new form *Plasmodium ovale*, the diseases they produce and the factors which govern the action of quinine, plasmoquin, atebrin and other drugs in their treatment and prevention. The results obtained at this laboratory, which has been visited by nearly all the best known malariologists and has been copied in other countries, have had a profound influence on malarial thought and action throughout the world. As a member of the Malaria Commission of the Health Section of the League of Nations, Col. James has taken an active part in its deliberations and recommendations and has visited most malarial countries, where his wide experience of the disease in all its aspects has enabled him to give valuable advice as to the methods which should be adopted to control this most widespread of all diseases. Col. James is still pursuing his investigations, and there is no doubt that he will continue to add to our knowledge of those minute parasites which are inoculated to man by mosquitoes, and attack the red blood corpuscles with such disastrous results. We wish him every success in his further endeavours.

U S National Academy of Sciences Awards

It is announced by Science Service that the Elliot Medal for 1931 has been awarded to the late Prof Davidson Black, of the U S National Academy of Sciences, for his researches on the skull of Peking man The medal and honorarium is awarded annually for work on zoology or palæontology The first award of the Charles Doolittle Walcott Medal and honorarium of 1,350 dollars of the Academy has been made to Dr David White, of the U S Geological Survey, in recognition of his work on the pre Cambrian algæ of the Grand Canyon of Arizona, which are among the very oldest of plant fossils Other awards just announced are Agassiz Medal, to Dr Bjorn Helland Hansen, of the Geophysical Institute, Bergen Norway, Public Welfare Medal, to Dr David Fairchild formerly of the U S Department of Agriculture and the Elliot Medal and honorarium of 200 dollars for 1930, to Dr G E Coghill Wistar Institute of Anatomy and Biology, Philadelphia

U S National Academy of Sciences

At the meeting of the National Academy of Sciences held in Washington on April 23–25, the following elections were made *Members* Prof V Bush, professor of electrical engineering and vice president of the Massachusetts Institute of Technology, Prof H S Gasser professor of physiology, Cornell University Medical College New York, Prof E N Harvey professor of physiology, Princeton University, Prof D R Hoagland professor of plant nutrition University of California, Prof E O Lawrence, professor of physics, University of California, Prof J F Norris, director of the research laboratory of organic chemistry Massachusetts Institute of Technology, Dr J H Northrop, biochemistry member of the Rockefeller Institute, Prof C Palache, professor of mineralogy, Harvard University, Dr T M Rivers pathology member of the Rockefeller Institute, Prof E Sapir, Sterling professor of anthropology and linguistics, Yale University, Dr E C Stakman plant pathologist U S Department of Agriculture, Prof H S Vandiver, associate professor of mathematics, University of Texas, Prof N Wiener, professor of mathematics, Massachusetts Institute of Technology, Prof S Wright, professor of zoology University of Chicago *Foreign associates* Prof V F K Bjerknes, professor of meteorology in the University of Oslo, Prof Robert Robinson, Waynflete professor of chemistry in the University of Oxford

Native Lands in Kenya

Any apprehension that the rights and sentiments of the Kenya natives in the matter of their lands are likely to be endangered by future government action, taken without full knowledge, should be allayed by the Report of the Kenya Land Commission which has now been issued with a White Paper stating the views of the Government (Cmd 4556, 11*s* and Cmd 4580, 2*d*) The appropriation of a part of the native reserve in the development of the Kakamega gold fields, notwithstanding arguments advanced in justification, aroused a feeling of uneasiness and a fear lest any policy of development, however short sighted, might in future be allowed to override obligations or measures framed to preserve the integrity and ultimate stability of native society The report of the Commission and the supporting body of evidence, which examine native claims relating to the land in detail, tribe by tribe, provide a permanent record defining the position in native land tenure, and at the same time by recommending that the Native Lands Board no longer exercise administrative functions but be devoted entirely to the office of protection—a recommendation accepted by the Government—ensures that, given a satisfactory constitution of the Board the interests of the native as determined in this combination of Domesday and Magna Charta, shall not go by default Further, the Board is given the power of veto over leases of land exceeding ten acres in extent The principle of leasing is to take the place of exclusion of land from the reserve and exchange, the land thereby remaining part of the reserve This, together with the requirement that native opinion shall be consulted is not only in harmony with the sentiment and practice of the natives but also avoids the more objectionable features which have hitherto appeared in land development

The Commission does not confine itself to present grievances and difficulties but has a clear view of the future development of the native Not only are 1,474 sq miles added to the native reserve in satisfaction of present claims but also a further area, totalling in all more than 2 000 sq miles, is to be set aside to meet present and future economic requirements In part of this additional area the system of tenure is to be more elastic than in the native reserve Tribal tenure will no longer be the only system, and the tendency of the native towards other forms of the economic unit will be recognised In other words, the native will be afforded an opportunity to habituate himself to a form of tenure more nearly in accord with the economy of European civilisation It is also suggested—though this recommendation will not be adopted until it has been considered by the local legislature—that certain reserve boundaries should be eliminated or modified to permit intertribal expansion and interpenetration The trend in these recommendations towards a modification of native culture is carried further in the stress laid on the necessity for a less wasteful use of the land and the references to proposals for restriction of the excessive number of cattle now carried As cattle form the currency and wealth of the native, should these proposals be given effect, he must needs accustom himself to some new form of wealth Up to the present, the increased resources which civilisation has brought to the native, in so far as they are not absorbed in the acquisition of an excessive number of cattle, would appear mainly to have been expended wastefully On the whole, it may be said that in its outlook on the future, the report, recognising that the native is entering upon a period of transition in which traditional culture must suffer modification, has suggested lines on which development will bring about the least dislocation and can most effectively be brought under an enlightened control

Petrol from Coal

THOSE who have maintained that the successful production of petrol from coal would prove of incalculable benefit to our long languishing coal industry will derive much satisfaction from a reply given in the House of Commons on May 17 Mr Mitcheson asked the Secretary for Mines if he could furnish an estimate of the increased consumption of coal in Great Britain which has resulted from the imposition of a duty on fuel oil The Secretary for Mines (Mr Ernest Brown), in reply, said Official information is not available But a short time ago I received a deputation from the Coal Utilisation Council and other bodies, which furnished detailed information, collected by various trade organisations This showed that, in terms of coal, there had been conversions from oil to coal and coal products, and business retained which it was stated would, but for the tax, have been lost to home produced fuels representing an annual rate of consumption of over 600 000 tons "

Sexual Selection in the Pheasant

THE Zoological Society of London has just received a noteworthy addition to its Gardens in a pair of Rheinhardt's Argus pheasants (*Rheinhardtius ocellata*) for this is one of the rarest of the pheasant tribe Those who are interested in problems of sexual selection will find these birds well worth thoughtful study, for they present a striking contrast with the commoner and better known Argus pheasant (*Argusianus*) This bird occupied a prominent place in Darwin's Descent of Man', on account of the enormous development of the secondary wing feathers, the like of which is seen in no other bird These feathers are also remarkable for their ornamentation, which consists of a series of ocelli which as Darwin pointed out, when they are displayed in the courtship attitude, look like a series of balls lying within a cup shaped socket, while the primaries are marked by a pattern of indescribable beauty The wings of Rheinhardt's pheasant lack any form of ornament, and in shape conform to the usual type of pheasant wing The tail feathers, however, are prodigiously long and marked by a pattern of considerable beauty This striking difference in the secondary sexual characters in these two birds is puzzling Nothing seems to be known of the nature of the display of *Rheinhardtius* in its amorous moods It is to be hoped, therefore, that the new arrivals will greatly enlighten us on this point The display of the wings in the Argus pheasant is unique, the two wings being widely spread so as to form an enormous circular fan completely concealing the rest of the body It affords an unanswerable argument to those who hold that birds in 'display' are not conscious of their finery

Mathematics and Cosmic Research

IN a lecture entitled World Gravitation by Kinematic Methods" given by Prof E A Milne before the London Mathematical Society on May 17, his hearers had the thrilling experience of seeing a possible model of the universe constructed before their eyes by a simple, but wholly brilliant application of apparently trivial mathematical methods Starting with Newtonian time, Prof Milne envisaged the behaviour of a set of particles of which the description given by an observer placed at any one of them would be the same as that given by an observer placed at any other The hypothesis leads to certain functional and differential equations from the solution of which Prof Milne deduced a statistical model of extreme elegance The astonishing result was obtained that in a given volume of the observer s space there are particles the velocity of which is arbitrarily near that of light On this, Prof Milne showed how a theory of cosmic rays and obscuring matter in interstellar space could be based The striking simplicity of the method and the far reaching character of its interpretations open up a new vista of possibilities for cosmic research

Demonstration of Television

ON May 15 a demonstration of the use of the cathode ray tube in television reception was given before the Electrical Association for Women at the showrooms of the Edison Swan Electric Co Ltd, London After a very clear and non technical exposition of the basic principles had been given, the B B C 30 line transmission was received The results obtained suggested that the cathode ray tube is capable of giving as good an image as the limitations of the transmission will permit There was very little flicker, owing to the large afterglow of the fluorescent material of the screen The latter was of the usual type giving a green image, the use of white fluorescent screens is not considered desirable at the low picture frequency at present in use, as the afterglow with these is much less The scanning is accomplished by means of two small oscillators giving voltages of saw tooth wave form and appropriate frequencies which are applied to the two pairs of deflecting plates, the incoming signals hold these oscillators in synchronism with the transmitter and also modulate the intensity of the electron beam Difficulty was experienced in keeping the picture steady during the demonstration, but this was attributable to the exceptionally bad local reception conditions It was stated that in normal circumstances the controls need not be touched during the whole transmission period of half an hour The advantages claimed for the cathode ray tube are that it is noiseless, that signals of good headphone strength only are required to operate it, and that by the alteration of a few minor circuit components it can be easily adapted to suit transmissions of different numbers of lines and picture ratios The last point is important in view of the uncertainty in the future development of television Suitable tubes can now be marketed at six guineas and this price could be substantially reduced if the demand became large enough As the auxiliary apparatus required is not excessive, and can be assembled from standard components, the system is quite practicable for domestic use

New Electric Lamps

IN a paper read to the Royal Society of Arts on March 7, Mr J W Ryde of the G E C Research Laboratories, Wembley, gave a full account of the working of the new electric discharge lamps The sodium discharge lamp is practically monochromatic and of a brilliant yellow colour Hence coloured objects illuminated by it all appear to be various shades of brown Its efficiency about 40 lumens per watt, although three times that of the ordinary filament lamp, is yet only about a tenth of the maximum possible yellow light that could be obtained for the same power It is well known that the efficiencies of all kinds of electric lamp vary with their life The problem of candle power maintenance is one that constantly engages the attention of every lamp manufacturer In spite of years of research the light output of incandescent filament lamps still drops by a certain amount after several hundred hours burning The candle power maintenance for the new lamps has now been raised to a reasonable figure, but it is recognised that considerable improvements are possible It is rapidly approaching that of the filament lamp At present there is no sign that the eminently simple and highly developed filament lamp will shortly be replaced by discharge lamps for purposes of indoor illumination, but it must be admitted that discharge lamps will play an ever increasing part in the future of electric lighting Already there are 65 street lighting installations for which these lamps have been adopted Street lighting is the one use of artificial lighting for which we have never produced enough light The use of the new lamps is an excellent opportunity of improving the lighting of our streets at little if any, increase in the cost

Importance of Deep Borehole Surveying

DESIGNERS of apparatus for surveying deep boreholes have in the past consistently underestimated difficult engineering problems necessarily attendant on such surveys On April 10, W E Bruges read a paper before the Institution of Petroleum Technologists in which he made some pertinent remarks on the usefulness of well surveys as an adjunct to drilling logs and geological data Geologists can utilise the results of accurate surveys for correcting underground contours, choosing such surface locations as will ensure economic spacing of wells in the oilsand below and making deductions as regards the formation as a whole from direction deviation and irregularities of the hole as portrayed by the survey Administration is facilitated by a knowledge of exact spacing of wells in an oilfield Decisions regarding drilling activities can be taken with confidence, and the risk of overcrowding, hence decreasing production, is minimised Recent experiments in Burma have shown that of available apparatus for this work, that designed and manufactured by Martienssen is the most satisfactory The instrument is fitted with a gyroscope for obtaining direction and two pendulums for inclination, results being recorded photographically It has the advantage that the gyroscope is unaffected by magnetic influences, while the pendulum method of obtaining inclinations allows a number of readings to be taken at one run Photographic recording of results means that the instruments below ground can be light, obviating necessity of following up gear, moreover, their relative places in the well can be photographed without disturbing position or setting

Automobiles Run by Charcoal Fuel

IN Italy, automobiles have recently been operated on a gas fuel made in transit from charcoal and steam It is recalled in a recent paragraph issued by Science Service, of Washington, D C, that similar experiments were made in France and other European countries several years ago The principle involved is the same as that used in the manufacture of some kinds of gas employed in operating stationary internal combustion engines A carbon containing material usually coal is heated, and then water in the form of steam is passed over it Carbon monoxide and hydrogen are formed in this process and both these gases burn with high heat output Mixtures of this sort are known as water gas or producer gas This gas can be used as fuel in internal combustion engines The drawback to using these gas engines in motor vehicles is the difficulty of carrying the fuel supply In permanent locations they can be used very effectively for power generation To a limited extent, vehicles that run on wood or charcoal and manufacture their own gaseous fuel as they go along are used commercially in France Science Service points out that this type of self propelled vehicle may become important in countries like France and Italy which have no petroleum supplies within their borders In the United States on the other hand, owing to the cheapness and availability of petroleum there would be no need for this kind of vehicle In those countries where imported oil supplies are likely to be interrupted in war time automobiles using charcoal fuel would have advantages.

Science and Industry in the U S S R

IN a recent publication entitled Organisation et Principes de L'Enseignement en U.R.S S" (Paris Hermann et Cie, 6 Rue de la Sorbonne) Prof Jean Trillat gives an interesting description of the relations between science and industry in Soviet Russia One of the most important transformations brought about by the Russian revolution has been the establishment of compulsory education, and this in turn has led to a considerable development of scientific studies Prof Trillat points out that in order to understand correctly the nature of educational and scientific progress in Russia, it is essential to remember that there such developments have been based on a materialistic philosophy The religious mysticism of pre War Russia has now been replaced by the mysticism of the machine The conception of science in Soviet Russia is that of an auxiliary to socialism Education figures as a definite part of the Five Years Plan, and the Educational Plan comprises a general scheme of public education, the preparation of technicians and scientific workers from among the working classes, together with a general scheme of scientific research and the establishment of numerous scientific institutes The author describes a number of these institutes which he visited including the physico technical Kombinat at Leningrad with its subsidiary institutes of physical chemistry and electro physics In addition, it has an experimental workshop of a unique character which manufactures scientific instruments for the Kombinat ' and other institutes Employing about 300 workers it is a half industrial and half scientific organisation Soviet industry has thus behind it very extensive means for scientific research, and the various problems, classified according to interest or urgency are investigated by the specialised chemical physical or electrical institutes

Chemical Researches in Czechoslovakia

EVER since the middle of last century, much chemical research work has been carried out at Prague Some of the investigations, notably Prof B Brauner's work on atomic weights and on the rare earth elements, attracted wide attention but much valuable if less spectacular, work was overlooked Few Czech men of science published in English journals, the majority of their researches appeared in the little read Czech publications To direct more attention to their achievements, Czechoslovak chemists founded in 1928 under the joint editorship of Profs Votoček and Heyrovsky the *Collection of Czechoslovak Chemical Communications*, in which the contributions were written in French or English Among the more interesting contributions that have appeared recently in this journal mention may be made of the discovery by Prof Křepelka and Dr Novotny that mercurous halides show marked triboluminescence the actual intensity depending on the conditions of preparation Prof Šimek has also made some observations on the curious electrical behaviour of fused tellurium dioxide In organic chemistry, Drs Landa and Machaček have described a new solid hydrocarbon, $C_{10}H_{16}$, to which they assign the name adamantane A series of researches by Prof Votoček and his collaborators has cleared up a number of points in connexion with the lesser known sugars such as rhamnose, rhodeose and fucose Prof Heyrovský has also published a series of papers (referred to in NATURE of March 10, p 385) dealing with his polarographic studies with the dropping mercury cathode

The Indian Chemical Society (1924–1932)

PROF B K SINGH's presidential address to the Indian Chemical Society (*Journal of the Indian Chemical Society*, vol 10, No 1, p 1, 1933) deals with "Optics in the Service of Chemistry ', and includes a review of recent work on optical rotatory power and rotatory dispersion, to which he has himself contributed He also records in a tabular form the growth of the Indian Chemical Society, during the nine years of its existence During the first five years the growth was rapid, but the Society has held its own during the more difficult years from 1929 until 1932 It now includes 360 fellows and 100 subscribers, and is publishing approximately 100 papers in each year, of which 750 pages are printed free of cost by the University of Calcutta Under these favourable conditions an income of about 10 000 Rs has usually provided a credit balance, and a reserve fund of 21 000 Rs has been built up in addition to a donation of 10,000 Rs from Sir P C Rây which is earmarked for the provision of a headquarters for the Society

Schlieren, Striæ or Streaks?

IN the January issue of the *Journal of Scientific Instruments* Mr T Smith, of the National Physical Laboratory, raises the question whether it is fair to Foucault to continue to describe the method he introduced for observing small optical differences of path by the name schlieren used for the method by Töpler in his paper of 1866 on the motion of singing flames Messrs Taylor and Waldram, who had used the term schlieren in their paper in the December issue of the *Journal*, point out that Töpler in giving the method that name made no claim to its invention but only to an extension of the use of it to general scientific investigations Would striæ or streaks be adequate equivalents of, and suitable alternatives for, *schlieren* ?

Uniformity in Bibliographical Particulars

REFERRING to recent correspondence on this subject (NATURE, 133, 380 March 10, 495, March 31, 1934), Mr A Windelbandt, bibliographer in the library of the Institute of Plant Industry, Leningrad, writes pointing out the practical value of accurately given bibliographical citations in articles and books Mr Windelbandt states that footnotes and other references are often given in such a way as to make it impossible to recognise the publication While the name of the author is quoted, the title of the article is often omitted and sometimes it is difficult to identify the journal owing to the manner in which the name is abbreviated The absence of the year and volume in the case of articles, and the place of publication and name of publisher in the case of books also renders it difficult for the reader to find the publication Lack of pagination, too, may lead to a lengthy search, if a volume has no special index.

Institute of Physics

THE annual general meeting of the Institute of Physics was held at the Royal Institution on May 15 After election of the officers and completion of the panel of the Board, it was announced that the following would take office on October 1 next: *President*, Sir Henry Lyons, *Vice President*, Prof W L Bragg, *Honorary Treasurer*, Major C E S

Phillips, *Honorary Secretary*, Prof J A Crowther, *New Members of the Board*, Dr Allan Ferguson and Mr R S Whipple In pursuance of one of the main objects of the Institute, namely, to urge the importance of Physics in Industry", the Board has decided to arrange a two day conference in the spring of 1935 on the applications of X ray structural analysis to various industries The main function of the conference will be to bring to the notice of industrialists what physics and physicists can do to help industry rather than the discussion of technical matters among experts The conference will be held in Manchester in conjunction with the local section of the Institute, and it is proposed to arrange an exhibition and visits in connexion with the meetings Full details will be announced in due course

Ancient Chinese Books on Materia Medica

In the year A D 659, an illustrated volume of materia medica was published in China It seems to have served until about 1061 when an extensive revision took place Prof Manzo Nakao has studied the history of this great compilation (Notes on Shao hsing Hsiao ting Ching shih Chêng lei Pei chi Pên tsao (The Ancient Chinese Materia Medica Revised in the Sung Dynasty Shao hsing period 1131 1162)" *J Shanghai Sci Inst* (3) 1, 1 9 May 1933) Much of the subject matter of the paper is of interest only to the Chinese historian but some of the descriptions show that the work was very thorough, and covered at least 22 volumes There were apparently several distinct revisions The medicines can all be recognised, and the historical investigation was stimulated by the possibility of reviving some of the ancient remedies under modern conditions

"World List of Scientific Periodicals"

The second edition of the "World List of Scientific Periodicals will be published in one volume by the Oxford University Press on June 30, at the price of £3 3*s*, but subscribers in advance will receive it at £2 2*s* Such subscribers resident in Great Britain or Europe must post their cheques before June 30, or if outside Great Britain or Europe before July 30 The new edition will contain titles and holdings of periodicals current right up to the end of 1933 The number of libraries the holdings of which are listed has been increased by 39, the number being 189 as against 150 Approximately 10,000 new titles have been added, the total number of entries amounting to 36,380 Each entry contains the title and place of publication of the periodical, the abbreviation, and the symbols for the libraries in which it is to be found and the dates of their holdings Further information can be obtained from the Secretary, "World List of Scientific Periodicals', c/o The Zoological Society of London, Regent s Park, London, N W 8

Announcements

The annual visitation of the National Physical Laboratory, Teddington, will be held on Tuesday, June 26, at 3-6 p m

The annual visitation of the Royal Observatory, Greenwich, will be held on Saturday, June 2 The new 36 in reflecting telescope will be opened by the First Lord of the Admiralty at 3 p m, and the Observatory will be open for inspection by invited guests at 3 30 p m

Prof Louis Martin has been elected director of the Pasteur Institute of Paris in succession to the late Dr Roux, with whom he had been closely associated

Prof J Barcroft will deliver the Stephen Paget Memorial Lecture at the annual general meeting of the Research Defence Society at the London School of Tropical Medicine and Hygiene, Keppel Street W C 1, on June 5 at 3 p m The subject of Prof Barcroft's lecture will be ' Experiments on Man '

The attention of chemists is directed by the Union Internationale de Chimie to the services rendered by the International Bureau of Physico Chemical Symbols in placing at their disposal pure organic compounds the constants of which have been determined with great accuracy The specimens supplied by the Bureau are guaranteed as possessing the constants of the values given in the published proceedings of the Bureau (*J Chim Phys*, vols 23, 25 27, 29 and 31) They can be obtained at cost price from the Secretary of the Bureau, Prof J Timmermans, University Brussels from whom further information can be obtained

The McGraw Hill Publishing Co, Ltd, has issued its catalogue for 1934, containing a classified list of its books on agriculture zoology and botany The catalogue can be obtained post free from Aldwych House, London, W C 2

Applications are invited for the following appointments, on or before the dates mentioned —An assistant in the Inquiry Bureau of the Building Research Station, Garston—The Secretary, Department of Scientific and Industrial Research 16, Old Queen Street, Westminster, S W 1 (May 30) A professor of botany at the University of St Andrews —The Registrar (May 31) An assistant keeper of Oriental printed books and MSS in the India Office Library—The Establishment Officer India Office, Whitehall, S W 1 (June 1) A lecturer (woman) in mathematics (biology or botany subsidiary), at the Darlington Training College—The Principal (June 4) A lecturer in physics and elementary science at the City of Leeds Training College—The Director of Education, Education Department, Calverley Street, Leeds (June 5) A curator of the Museum and Art Gallery at Barking—The Town Clerk, Town Hall, Barking (June 7) An assistant agricultural organiser to the Northamptonshire County Council—The Secretary for Education, County Education Offices, Northampton (June 9) A professor of electrical technology at the Indian Institute of Science, Bangalore, India—The Director (Aug 1) A University professor of mining at Imperial College of Science and Technology—The Academic Registrar, University of London, S W 7 (Jan 14, 1935)

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Radio Exploration of the Ionosphere

(*a*) *Measurement of the earth's magnetic field in the ionosphere*

The discovery[1] of magneto-ionic doubling of wireless echoes returned from the ionosphere and its explanation[2] in terms of the theory of double refraction have provided us with a method of estimating the intensity of the earth's magnetic field at the level from which the waves are reflected. The way in which the earth's magnetic field is related to the observational data was indicated by Appleton and Builder, who showed that under conditions of quasi-longitudinal propagation relative to the direction of the magnetic field, we have

$$H = \frac{2\pi m}{e}(f_e - f_o) \qquad (1)$$

where H is the total magnetic intensity, f_e and f_o are respectively the critical penetration frequencies of the extra-ordinary and ordinary waves for any particular region, and e and m are the charge and mass of an electron. For conditions of quasi-transverse propagation, on the other hand, the corresponding formula is

$$H = \frac{2\pi m}{e}\left(\frac{f_e^2 - f_o^2}{f_e}\right) \qquad (2)$$

It was further shown by Appleton and Builder that their experimental results, obtained under conditions of quasi-transverse propagation, agreed approximately with (2) when the value of the earth's magnetic field at the ground was used for H, so that their observations could be interpreted as indicating either the approximately quantitative correctness of the magneto-ionic theory or that the magnetic field in the ionosphere does not differ very markedly from its value at ground level.

If we assume the quantitative correctness of the magneto-ionic interpretation of the results, it is obvious from equations (1) and (2) that we have here a method of measuring the magnetic field in the ionosphere. During the past year, I have therefore made as careful measurements as possible of the value of H for the upper ionised region during nocturnal conditions when critical frequency measurements are most reliable, my object being to look for small variations of H such as might be caused by the upper atmospheric currents envisaged in present-day theories of terrestrial magnetism[3].

The detailed examination of these results is still in progress, but one result of interest has emerged from the first series of two hundred measurements. The average value of H calculated from (2) is found to be 0.42 gauss. Now the value of the earth's total magnetic field at the surface of the earth in south-east England is 0.467 gauss, so that the radio observations suggest that the average magnetic field in the ionosphere is about 10 per cent less than its value at the ground.

Now, according to Schmidt, the earth's magnetic field intensity above the surface may be expressed, as a first approximation, by $H_0\,(1 - 3h/R)$ where H_0 is the ground value, h the elevation and R the earth's radius. The values of the magnetic field at 200 and 300 km. above the earth's surface in south-east England should therefore be 0.42 and 0.40 gauss respectively. It will be seen that the value obtained by the radio methods is of about this order of magnitude.

(*b*) *A new method of ionospheric investigation*

One of the fundamental quantities measured in the study of the ionosphere is the group time for a signal to travel to the stratum of reflection and back to the ground. To measure such a group time, we must impress some kind of mark on the signal in order to recognise it on its return. Now the essential characteristics of an electric wave are frequency and amplitude, and the two basic methods of group time measurement are thus those involving frequency modulation and amplitude modulation. It must not be assumed, however, that in their simple forms they always represent the most convenient ways of marking a signal for group time measurements, and I have recently found that there are sometimes advantages in combining the methods so as to produce a frequency change on a pulse emitter. It will readily be seen that in doing this we extend the frequency range examined in the experiment and obtain, in effect, information comparable with that which we should get with an extremely brief pulse. This means that we can investigate the structure of echoes which are normally unresolved.

As an example of the use of this combination method, as I propose to call it, let us consider the case of an unresolved magneto-ionic doublet. If the mean frequency of the emitter is varied continuously through a sufficiently large range, we get interference effects in the echo itself, so that any component amplitude varies through a series of maxima and minima. If in this case, a linearly polarised receiver aerial is used, we have

$$c\,\frac{\Delta n}{\Delta f} = P'_o - P'_e \qquad (3)$$

where P'_o and P'_e are the equivalent paths of the ordinary and extraordinary waves, Δn the number of interference fringes produced by a change of frequency Δf and c is the velocity of light.

When apparatus is available for providing automatic maintenance of sender and receiver tuning during the frequency change, such as that first described by Gilliland, the usefulness of the combination method may be strikingly demonstrated. For example, in a test carried out at Slough at 1530 on March 8, 1934, using an apparatus of similar principle designed by Mr. L. H. Bainbridge Bell, an alteration of mean frequency of from 4.0 to 4.2 mc./s. produced five interference fringes in a first order F region reflection. This corresponds to an equivalent path difference for the two magneto-ionic components of 7.5 km., or to a difference in equivalent height of 3.75 km. It is obvious that differences in equivalent height of 1 km. or less can be detected in this way.

The work described above was carried out as part of the programme of the Radio Research Board of the Department of Scientific and Industrial Research.

Atomic Disintegration by 'Non-Capture'

It has been assumed[1] that the nucleus of an atom may be disintegrated by either (1) a process in which the projectile (A), which is another nucleus, is captured, or (2) one in which it is not captured

$$(1)\quad A + B \rightarrow (AB) \rightarrow C + D$$
$$(2)\quad B \rightarrow C + D$$

These are illustrated in Figs 1 and 2

While the evidence for the occurrence of disintegration by capture is so good as to be undisputed, that for non capture is less convincing

Probably the best evidence for disintegration by non capture is that given by photographs of tracks of the disintegration particles C and D, where the projectile A is a neutron and B is a nitrogen nucleus Thus Feather, in a discussion of his excellent work with neutrons, says of these about thirty resulted in disintegration, more than half of the latter without capture of the neutron"[2]

In this laboratory about a hundred disintegrations of nitrogen nuclei by neutrons were photographed[3], and of these, 26 were of such high quality as to give good measurements For 17 of these it was found that the straight line (a) for A passes directly through the source These may be assumed to represent *disintegrations by capture*

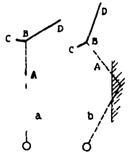

FIG 1 Capture

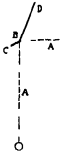

FIG 2 Non-capture

The remaining nine might be considered as possible cases of non capture However, in one of these the tracks C and D were turned in such a way as to prove that the neutron could not have come in a straight line from the source, that is, it was a scattered neutron

The values for the velocity of the incident neutron, assuming non capture, were calculated from the best five photographs both by our equations involving rest masses (3) or including the complete relativity relations (4) as given below

$$V_A = \frac{M^2 + 2m_A\,(E_C + E_D + E_m)}{2m_A\,M\cos\alpha} \qquad (3)$$

or

$$V_A = \frac{M}{2m_A\cos\alpha} + \frac{(E_C + E_D + E_m)}{M\cos\alpha}, \qquad (3)$$

where V_A and m_A are speed and mass of projectile, M is magnitude of resultant momentum of B and C, E_C and E_D are their kinetic energies, E_m is energy corresponding to increase of mass in the reaction, or $E_m = c^2\Delta m$, α is angle between V_A and direction of $\bar{M}$

It is assumed that a γ ray is not emitted However, an approximate solution may be obtained if the term $E\gamma$ is added to the quantity between the parentheses, since the momentum of the γ ray is, in general, negligible

The relativity equation, similar in form to (1), may be written

$$V_A = \frac{c\,(w^2 - K^2) + 2k_A cK}{2k_A w\cos\alpha} \qquad (4)$$

in which $k_A - k_A' \equiv K$ and $\frac{k_A\bar{V}_A}{c} - \frac{k_A'\bar{V}_A'}{c} \equiv w$

and c is the velocity of light

It was found (a) that the velocities thus calculated were *very much higher than those of any known neutron* However, if (b) it is assumed that the disintegrations correspond to Fig 1b, that is, the neutron is first scattered and then gives a disintegration by capture, the neutron velocities for the nine disintegrations are not only of the right order of magnitude but also the distribution curve which plots number of events against velocity of the neutron, is *the same as that obtained for the disintegrations* caused by neutrons directly from the source

Thus the evidence seems to indicate that these disintegrations also occurred with capture of the neutron It seems reasonable to conclude that there is at present no evidence which proves that any nucleus has been disintegrated by a non capture collision Obviously this does not prove the non occurrence of disintegrations of this type

We wish to thank Prof A C Lunn for his co operation

X-Ray Photographs of Crystalline Pepsin

FOUR weeks ago, Dr G Millikan brought us some crystals of pepsin prepared by Dr Philpot in the laboratory of Prof The Svedberg, Uppsala They are in the form of perfect hexagonal bipyramids up to 2 mm in length, of axial ratio $c/a = 2\ 3 \pm 0\ 1$ When examined in their mother liquor, they appear *moderately birefringent and positively uniaxial*, showing a good interference figure On exposure to air, however, the birefringence rapidly diminishes X ray photographs taken of the crystals in the usual way showed nothing but a vague blackening This indicates complete alteration of the crystal and explains why previous workers have obtained negative results with proteins, so far as crystalline pattern is concerned[1] W T Astbury has, however, shown that the altered pepsin is a protein of the chain type like myosin or keratin giving an amorphous or fibre pattern

It was clearly necessary to avoid alteration of the crystals, and this was effected by drawing them with their mother liquor and without exposure to air into thin capillary tubes of Lindemann glass The first photograph taken in this way showed that we were dealing with an unaltered crystal From oscillation photographs with copper $K\alpha$ radiation, the dimensions of the unit cell were found to be $a = 67$ A, $c = 154$ A, correct to about 5 per cent This is a minimum value as the spots on the c row lines are too close for accurate measurement and the *c* axial length is derived from the axial ratio The dimensions of the cell may still be multiples of this Using the density measured on fresh material[2] as 1 32 (our measurements gave 1 28), the cell molecular weight is 478,000, which is twelve times 40,000, almost exactly Svedberg's value arrived at by sedimentation in the ultracentrifuge This agreement may however be quite fortuitous as we have found that the crystals contain about 50 per cent of water removable at room temperature But this would still lead to a large molecular weight, with possibly fewer molecules in the unit cell

Not only do these measurements confirm such large molecular weights but they also give considerable information as to the nature of the protein molecules and will certainly give much more when the analysis is pushed further From the intensity of the spots near the centre, we can infer that the protein molecules are relatively dense globular bodies, perhaps joined together by valency bridges but in any event separated by relatively large spaces which contain water From the intensity of the more distant spots, it can be inferred that the arrangement of atoms inside the protein molecule is also of a perfectly definite kind although without the periodicities characterising the fibrous proteins The observations are compatible with oblate spheroidal molecules of diameters about 25 A and 35 A arranged in hexagonal nets which are related to each other by a hexagonal screw axis With this model we may imagine degeneration to take place by the linking up of amino acid residues in such molecules to form chains as in the ring chain polymerisation of polyoxy methylenes Peptide chains in the ordinary sense may exist only in the more highly condensed or fibrous proteins, while the molecules of the primary soluble proteins may have their constituent parts grouped more symmetrically around a prosthetic nucleus

At this stage, such ideas are merely speculative but now that a crystalline protein has been made to give X ray photographs, it is clear that we have the means of checking them and, by examining the structure of all crystalline proteins, arriving at far more detailed conclusions about protein structure than previous physical or chemical methods have been able to give

[1] G L Clark and K E Korrigan (*Phys Rev* (ii) 40 639 1932) describe long spacings found from crystalline insulin but no details have been published

[2] J H Northrop *J Gen Physiol* 13, 739 1930.

IT is now some time since we first took X ray powder photographs of crystalline pepsin kindly sent by Prof J H Northrop, but no really satisfactory interpretation of these photographs presented itself because they show features which we have learnt recently to associate with the fibrous proteins[1] even single crystals so far as we could judge with the minute crystals available, appeared to give results similar to those produced by many crystals in random orientation The two chief rings have spacings of about 11 5 A and 4 6 A at ordinary humidity, corresponding to the 'side chain spacing' and the 'backbone spacing', respectively, of an extended polypeptide[1].

It was difficult, of course, to reconcile such findings with external morphology and the Law of Rational Indices, but the photographs of Bernal and Miss Crowfoot, taken before the degeneration which we now see the crystals must have undergone on drying, clear up this long standing problem at once Furthermore, their photographs tend to confirm the suggestion[2] that the numbers 2, 3, 4, and 6 occurring in Svedberg s multiple particle weights are fundamentally of *crystallographic* significance, even though their conclusions to date appear to be against the chain mechanism proposed for the building up of the various crystallographic groups[2]

We are left now with the paradox that the pepsin molecule is both globular[3] and also a real or potential, polypeptide chain system, and the immediate question is whether the chains are formed by metamorphosis and linking up of the globular molecules, or whether the initial unit is the chain itself which is afterwards folded in some neat manner which is merely an elaboration of the intra molecular folding that has been observed in the keratin transformation[1] What is either an exceedingly valuable clue or else only a fantastic coincidence is found in the fibre photograph of feather keratin[4] a study of which will be published shortly , for if, as Bernal thinks, the pepsin molecules are piled, perhaps in a screw along the hexad axis, their length in this direction is 140/6, that is, about 23½ A , which is almost exactly the strongest period along the fibre axis of feather keratin, a period which is again repeated probably six (or a multiple of six) times before the fundamental period is completed ! The innermost equatorial spot of the feather photograph also corresponds to a side spacing of about 33 A (though this is probably not the maximum side spacing) which again is in simple relation to the side dimensions of the pepsin unit cell As just said, these resemblances may be only accidental, but we cannot afford to overlook anything in such a difficult field and it is not impossible that we have here an indication of how very long *but periodic*, polypeptide chains can arise by the degeneration and linking up of originally globular molecules

Transitions to Optical Levels in the Argon *L* X-Ray Absorption Spectrum

THE so called fine structure of X ray absorption edges is caused by the possibility of transition of an inner electron to *different* upper levels, these levels being more or less discrete for the lowest energies and approximately continuous for the higher ones In the ordinary X ray region, the fine structure observed with crystalline absorbers usually extends over more than 100 v from the main edge It was pointed out by Kronig[1] that in this case the discrete character of the upper states 'may be considered as due to the wave character of the motion of a 'free' electron in the *periodic field* of the lattice This conception has been successfully applied to many cases[1]

In some cases, however, it seems more natural to visualise the upper states in a slightly different way, namely, as optical orbits' of the *single* atoms[3] This would seem to apply in the first place to monatomic gases like argon, and perhaps also more or less to some cases of fine structure observed at small distances (<20 v) from the main edge in solids and molecular gases

A narrow fine structure of the argon (18) *K* edge found by Coster and van der Tuuk[4] was explained by the authors in this way They remarked that in this case the upper levels in question should lie very close to the optical levels of potassium (19), as the absence of the inner electron will make itself felt in the outer regions of the atom in much the same way as an increase of the nuclear charge by one unit Owing, however, to the small energy resolution in the ordinary X ray region, the authors were not able to establish the predicted correspondence conclusively, though they showed it to be a probable explanation for the experimental results

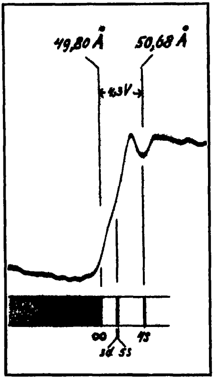

FIG 1 Comparison of the argon $L_{II\,III}$ absorption spectrum (upper curve) with the optical spectrum of potassium (lower figure) on the same energy scale

Now recently I have photographed the absorption spectra of some gases and vapours in the ultra soft X ray region by the plane grating method, giving a resolution of about 0 5 v The vacuum spectrograph[5] was filled with the gas at a pressure of 0 5 mm mercury or less, the X ray tube being closed against the spectrograph by a thin film of cellulose nitrate

In Fig 1 the photometric record of one of my plates for argon (18) is reproduced together with the energy spectrum of potassium (19) on the same scale It will be seen that the correspondence between the two figures to be expected on the above considerations seems to exist, provided the *p* levels of potassium be omitted These are not indicated in the figure, but as they would lie between successive *s* levels, their presence would make the correspondence less satisfactory Now this omission of the *p* levels is just what is to be expected *if the ordinary selection rules apply* to this case, as the inner electron removed is itself a *p* electron and so should pass over to *s* and *d* levels only. Of course the multiplicity is higher in our case than with the spectra of the alkalis, but we may neglect the spin altogether[6] and consider the argon atom approximately as a certain central field of force in which the absorbing electron in question jumps from one 'orbit' to another

From Fig 1 and other analogous curves, the number of absorption electrons per atom' or strength of the virtual oscillator corresponding to the transition $2p \rightarrow 4s$ may be estimated at about 0 005, which seems a reasonable value from a theoretical point of view[6] Regarding the experimental width of this absorption line, it may be remarked that it is not due to insufficient spectroscopic resolution, but represents a real phenomenon inherent to X ray absorption and emission lines and connected with the existence of the Auger effect, etc

Analogous fine structures are present in other cases[5] The full report is to appear in *Physica*

Isotope Effect in the Band Spectrum of Aluminium Hydride

IN a previous letter[1], we published some preliminary results from an investigation on the band spectra of AlH and AlD As a remarkable result, we stated that the ratio of the reduced masses of both molecules, $\rho^2 = \frac{\mu_{AlH}}{\mu_{AlD}}$, has a mean value 0 51897, deviating considerably from the value $\rho^2 = 0\ 51848$ to be expected when applying the known atomic weight figures to the general expression of the reduced mass of diatomic molecules $\mu = \frac{Mm}{M + m}$, M and m representing the atomic weights of aluminium and the respective hydrogen isotopes

Considering possible causes for this discrepancy, we now find it most probable that it arises from an uncritical application of the expression for μ In the case of a metal hydride, where the centre of gravity is situated close to the heavy metal nucleus, a small correction in the effective moment of inertia I arises from the contribution of the electronic system To a high degree of exactness the moment of inertia can be written as follows

$$I = \mu r^2 + \iota_e,$$

where μ refers to the reduced mass of the molecule, deduced as before, and ι_e represents the moment of inertia of the electronic system in the metal atom Assuming that the electronic system partakes fully in the rotation and vibration of the molecule, that is, suppose there is no lag of the inner shells in aluminium, a rough estimation of this correction on the basis of classical theory with electronic orbits leads to $\rho^2 = 0 5190$, in good agreement with the spectroscopic value A more refined calculation of the electronic effect, using methods given by Thomas[2] and Hartree[3], leads to $\rho^2 = 0 51892$ As a matter of fact, this value is in surprising agreement with our latest value, $\rho^2 = 0 51889$, obtained from recalculation of the spectrum, based on improved measurements

Enzyme Catalysis of the Ionisation of Hydrogen

THE well known analogy between the colloidal metallic catalysts and certain enzymes early suggested to us the inclusion of the latter in our survey of catalysts for the ionisation of hydrogen[1], and the work of Stephenson and Stickland on hydrogenase[2] indicated the most promising material for investigation Work has now been in progress for some time on several strains of *Bact Coli* and on *Bact Acidi Lactici*, and we wish to make a preliminary report of our results—the more so as the announcement of a forthcoming paper by Hughes, Yudkin Kemp and Rideal includes a brief reference to work which may be following parallel lines

We have found that these bacteria are able, like platinum black, to catalyse the reaction

$$HD + H_2O \rightarrow H_2 + HDO,$$

and in the case of *B Acidi Lactici* we have measured the first order velocity constant ($K = \frac{1}{t} \ln \frac{C_0}{C}$) at 37° for a known number of organisms

Number of Organisms		Partial Pressure of Hydrogen	Initial Atomic per cent Diplogen	K in min $^{-1}$
Total 5×10^{11}	Living $2 2 \times 10$	360 mm	1 06	0 0065

The 'total' number of organisms was estimated by comparison with standard (killed) suspensions, the number living by dilution and agar plate count The bacteria, which in each case were washed three times in 0 85 per cent saline (with centrifuging) and finally aerated before use, were presumably in the 'resting' state (so far as the living are concerned) Partially 'heavy' hydrogen and the (de aerated) saline suspension of the bacteria were the only materials present in the (sealed) reaction vessel, which was vigorously shaken

Breathing Movements of Whales

WHALES, when breathing, usually keep on the move, the purpose of this letter is to explain why All aquatic air breathing creatures have to contend with the risk of water entering their lungs Although the blow holes of whales are valvular and situated on the highest part of the head, these animals, usually, can only breathe with safety when their blow holes are at some height above the surface of the sea

Owing to their shape, whales usually can only bring their blow holes into a favourable position for breathing by coming up to the surface obliquely at some speed and as they only get time to take a single breath, they have to repeat the performance again and again The following extract from a paper by Racovitza[1] shows that this, in fact, is their usual behaviour

The whale, having returned to the surface, after a long immersion, emits a prolonged expiration, makes a short inspiration, dives a little, re appears to breathe, dives again, and then many times in succession, then it makes a long inspiration and plunges into the depths for a considerable time" Again, he says, 'the number of these intermediate immersions before sounding varies according to the species In general, whale bone whales execute but a few, the toothed whales very many In all cetaceans, however, they are characterised by the following (2) the interval between the re appearances is very short, (3) the animal dives only to a slight depth, (5) the whale, during the time it is under water, progresses quite rapidly, usually in a straight line"

The effort that whales require to make on these occasions seems to depend on the roughness of the sea, and the height of the animal's crown, on which the blow holes are situated, above the water The Greenland whale, or Bow head, is well off in this respect, owing to its high crown It is able to lie motionless with its blow holes a foot or two above the surface

Exceptionally, whales sometimes breathe while lying motionless at the surface This generally occurs where the sea is very smooth and applies more particularly to the Greenland whale and narwhal—whales that habitually frequent the ice

The Greenland whale frequently breathes while motionless or nearly so Indeed, in narrow situations it is difficult to see how it can do otherwise. Scoresby[2] says, 'Several (Greenland) whales being astir and the weather fine, we sent all our boats in pursuit These whales were rather numerous, four or five being sometimes seen at a time The usual stay of a whale at the surface for breathing is about two minutes, seldom much longer, but it was a remarkable circumstance in the conduct of these whales, that they remained regularly from five to fifteen minutes at a time, and some, nearly half an hour before descending out of sight During this long interval they were generally quite motionless."

Greenland whales, when there is no ice, probably behave in the usual way This in fact seems to be the case Sutherland[3], referring to Davis Strait and the 'fall' of the year when there is no ice, says, Whales are very numerous and, at the same time, they are so wild that it is almost impossible to approach them"

Narwhals are sometimes seen breathing while motionless, particularly in very fine weather and in narrow situations These animals are provided with a subcutaneous chamber connected with their single blow hole which may help to prevent water reaching their lungs Scoresby[4] says, "When respiring at the surface, they [narwhals] frequently lie motionless for several minutes with their backs and heads just appearing above the surface" Where there is no ice they probably behave in the usual way

Blue whales are occasionally seen amongst the ice, they seem to avoid narrow situations and, when breathing, are usually on the move Scoresby says It [the Blue whale] seldom lies quietly on the surface of the water but usually has a velocity of from four to five miles an hour"

In the Greenland Sea, outside the ice I have only seen Bottlenose whales breathing while motionless This occurred alongside and in lee of the ship where the sea was very smooth The weather was fine at the time They formed an interesting sight, and their breathing made a peculiar noise

Active and Inactive Forms of the Hormone Promoting Comb Growth

FUNK[1] has shown that the hormone promoting comb growth can only be extracted from the urine of men in the presence of large quantities of acid (see also Kabak[2]) By means of acid extraction I demonstrated the presence of about 40 capon units per litre in hundreds of batches of normal urine but I could not detect even 20 units per litre by injecting the fresh concentrated urine itself

I concluded that the hormone must be present in the urine in an inactive form, and therefore tried to isolate it in this state This has been accomplished by extracting fresh urine of men at its original *p*H (5 3) by means of butanol When testing this extract (after having taken it up in oil) the reaction of the capons was negative to doses which would have corresponded to 15 and 12 units per litre respectively From this it was supposed that the butanol extract contained the inactive form of the hormone for which I was seeking 240 c c of this extract, corresponding to 15 litres of urine, were boiled for 8 hours after the addition of 29 gm of trichloracetic acid The butanol was then washed with 10 per cent caustic soda and with distilled water, after which it was transferred into oily solution and tested in capons The product gave positive reactions in quantities equivalent to 27 and 40 capon units per litre

It is thus evident that the hormone promoting comb growth is present in the urine of men in an inactive form, in which it can be extracted by means of butanol The inactive form can be turned into the active one by boiling the extract with trichloracetic acid

A Provitamin A other than Carotene?

A TURBOT concentrate estimated by spectrographic and colorimetric tests to contain 60 per cent vitamin A (the vitamin A of Carr and Jewell[1] taken to be 100 per cent) was irradiated in spectroscopic alcohol in the complete absence of air with light of wave length 300–390 mμ Solutions containing 0 0011 per cent vitamin A were found to be only slightly affected by exposures up to three hours' duration whilst solutions containing 0 00011 per cent were remarkably sensitive Solutions of this latter concentration were irradiated in lots of 60 ml for different periods and kept stirred during irradiation by a magnetic stirrer After irradiation of one lot it was evaporated *in vacuo* at 50° and brought to such a concentration as was equivalent spectroscopically at 328 mμ to a solution containing 0 0011 per cent vitamin A Its absorption curve in the ultra violet and its blue value were then determined

Irradiation up to three minutes caused a decrease in *E* and blue units, so that the concentrate which had a percentage vitamin A of 60, now shows a percentage of 30 Further irradiation caused a progressive increase in the spectroscopic and blue values, reaching a maximum after twenty one minutes irradiation when for the concentrate, a percentage vitamin A of 140 was given by the spectroscopic value, 130 by the blue value Further irradiation caused rapid destruction of the vitamin

The non irradiated concentrate in the blue value test showed a band at 565 mμ, after three minutes' irradiation the band had changed to 575 mμ, after twenty one minutes, 575 mμ Thus the chromogen responsible for the 565 mμ band is the precursor of the 575 mμ chromogen, which is either a purer vitamin A than that of Carr and Jewell or a sterol with very much higher spectroscopic and colorimetric values

A report of these experiments has been sent to the *Biochemical Journal*

China and the Maya Calendars

WITH reference to the note on the above subject in NATURE of January 13, p 68, the resemblances in the calendar systems seem to be exaggerated by Dr Kiang The Chinese day count follows the numbers 10 and 12 (L C M = 60) The Maya follows the numbers 13, 20 and 365 for the calendar round' of 52 vague years and the further factors 18 and 20 for the long count Apart from the mere principle of a continuous day-count with more than one concurrent numerator, the agreement is slight

A more striking 'coincidence' is the use of the 5 epagomenal days and the taboo during them, which agrees with Egyptian practice and so lends support to Prof Elliot Smith's diffusion theory

Research Items

Prehistoric Lincolnshire The first section of a survey of present knowledge of the prehistoric archæology of Lincolnshire by Mr C W Phillips is published in the *Archæological Journal*, 90 The county falls into well defined geographical divisions, of which the most important are the marked oolite ridge called Lincoln Edge and the Wolds There are two areas of low country, one, to south and east on the shores of the Wash, continuing round both sides of the Wolds and the other, the Isle of Axholme, on the west side of the outfall of the Trent into the Humber Although the geology of the lower grounds is not very conducive to prehistoric occupation, one of the surprises of the county archæology is the relatively considerable occupation of low lying lands at several periods There is little evidence of occupation of the county area in lower and upper palæolithic times In the microlithic period two areas of exposure of sand show evidence of occupation Risby Warren being regarded as the type site of Great Britain for this period In the neolithic period the discovery of nine, or possibly ten, long barrows on the Wolds has been one of the recent archæological surprises The builders were Windmill Hill folk Other neolithic objects except finds in the neighbourhood of Grantham and at Risby Warren belong to the Wolds The distribution of Early Bronze Age objects is such as might be expected when intruders from the North Sea were making their way into the county by the Humber and the Wash The distribution of beakers and daggers is entirely riverine, and there is evidence of only one landing on the coast The destruction of round barrows owing to agriculture has been great The majority stand on high ground away from the settlements In the Middle and Late Bronze Ages the distribution of the population did not differ materially from that of the early period of metal, being confined mainly to the valleys In the middle period the whole of Lincoln Edge from one end of the county to the other was occupied A novel feature was the beginning of the concentration around Brigg where a great dugout boat was found in 1886 Among gold objects found in the county two are important a gold armlet, now lost, and a torc with Y shaped section from the Isle of Axholme

Pre-Conquest Mexico In the fifth issue of *Ibero Americana*, the publication of the University of California Press which is devoted to the study of material relating to the geography or ethnology of Central America in early Spanish records, Dr Carl Sauer has reconstructed, so far as is possible, the distribution of aboriginal tribes and languages in north western Mexico, thus supplementing, and in some instances revising, the linguistic researches of Swanton, Thomas and Orozco y Berra The observations used are drawn from records dated between 1531, when Nuño de Guzman first entered the country, and 1768, when the Jesuits were expelled and the mission system began to come to an end It is not possible to confine the study of pre conquest conditions within narrower chronological limits, owing to the fact that while in the north Spanish influence was not felt until the end of the seventeenth century, in the south catastrophe overtook the native peoples at once Indians from central Mexico settled the country, in part as a replacement of the native on the land, in part as a baboo class intervening between the Spaniards and the indigenous population Wars, in which they suffered from the attacks of both sides, and the exploitation of the mines, were alike disastrous to the sedentary Indians, while in Sinaloa and Nayarit aboriginal conditions are impossible to recover owing to the establishment of *encomiendas* (villages granted as private possessions to individuals) in the sixteenth century, the grantees making good any deficiency in the labour supply by the importation of labour from outside, in some instances negro labour which rapidly brought into existence a mulatto population It would appear that the Aztec migration myth which asserts a wide spread distribution of Aztec people and culture, rests on the fact that Aztec speech was introduced as a matter of convenience into non Aztec areas by colonial settlers The Aztec place names quoted in evidence are in reality translations of indigenous names

Characteristics of Tumour Cells Prof Warren H Lewis summarises in Some Characteristics of Tumour Cells (News Bulletin, Carnegie Institution Washington) the principal differences between normal and tumour cells In the body, malignant cells show uncontrolled disorderly growth lack of useful function, rapid cell death, transplantability from animal to animal, injurious effect on normal tissues and acid metabolism The differences seen *in vitro* are more granular cytoplasm more refractive fat globules, smaller mitochondria, and no increase in neutral red granules The nuclear membrane is thicker, nucleolar material increased and the nucleus itself appears to be more granular The cells migrate more readily, and their shapes and general character in colonies help to differentiate them from one another and from the normal cells

Life-Cycle of a Human Echinostome Marcos A. Tubangui and Antonio M Pasco (*Philippine J Sci* , 51, 1933) have elucidated the life history of *Echinostoma* (*Euparyphium*) *ilocanum* a small human intestinal trematode discovered by Garrison (1908) in Manila The life cycle conforms to that usual for echinostomes Two molluscan intermediate hosts are involved , in the first, a small fresh water planorbid, are found the miracidium sporocyst redia and daughter redia stages, and from the last named the cercariæ escape and encyst in any of the common fresh water snails which form the second intermediate host The adult flukes were obtained by feeding encysted cercariæ from these snails to rats, a cat and two monkeys and it is concluded that human infestations are brought about by consumption of raw or insufficiently cooked snails harbouring the encysted cercariæ The limited geographical distribution of the fluke is explained by the observation that the habit of using raw snails as food is found only in the north west provinces of Luzon, that is, among the Ilocanos, The various stages are described and figured

Histology of Eye Mutants in *Gammarus* A series of colour mutations' in the eyes of the Amphipod *Gammarus chevreuxi* are well known to be inherited as Mendelian differences Wolsky and Huxley (*Proc*

Roy Soc , B, 114 364) have made a study of the histology and development of the eye in the various mutant types in comparison with the normal Eye colour mutants, such as red and no white, differ from normals only in pigmentation, while such eye structure mutants as albino and colourless show a structure which is markedly abnormal, the animals being blind The genes for the latter class of mutants might be likened to timed bombs which completely derange the development of the eye and adjacent structures The rate of development of the optic tract is slowed down and inhibited, especially in its distal portion, the retinular cells are deficient in number they fail to arrange themselves in groups of five and soon degenerate, while the interstitial cells show signs of hypertrophy The crystalline forming cells fail to form normal cones In explaining these results the following principles are utilised (1) alteration in the rate of a differentiation process, leading to inhibition , (2) an intensity gradient in the amount of inhibition , (3) development proceeding centrifugally in the optic tract , (4) struggle between parts leading to failure of the retinular cells and multiplication of the interstitial cells , (5) effect of the nervous system In the albino mutant, both the black melanin and red lipochrome pigments are absent because the retinulæ in which these pigments normally appear are suppressed

Chromosome Structure in *Allium* A detailed investigation of chromosome structure in *Allium*, by Prof T K Koshy (*J Roy Micro Soc* , 53, No 4), introduces several new conceptions The work of several other investigators is confirmed in showing that the chromosome is a double structure throughout the mitotic cycle Koshy goes further and shows that the chromomeric appearance frequently found in chromosomes is due to the close intertwining of two spiral chromonemata He also finds that the spiral of the chromonema is reversed at the point of the spindle fibre attachment constriction This is the point where the daughter chromosomes begin to separate in metaphase But before this has happened, each daughter chromosome has undergone a split into two chromonemata This is not a straight longitudinal split, but a spiral line of cleavage At about the time this spiral cleavage appears, the two daughter chromosomes in which it occurs unwind from each other just before the anaphase This unwinding proceeds from both ends towards the constriction where the reversal of the spiral takes place, this null point being regarded as a fulcrum The anaphase and telophase chromosomes thus contain two spiral chromonemata *owing to the spiral split in prometaphase* In late telophase the two threads are found to approximate very closely due to the elongation of the chromosomes, and their duality is thus obscured, but it reappears in the following prophase These observations have significant bearings on various current views in cytology and genetics They uphold the chromonema as against the chromomeric theory, and strongly support the generally accepted view that the anaphase and telophase chromosomes are double

New Gentians Capt F Kingdon Ward writes on "Some New and Rare Gentians" in the *Gardeners' Chronicle* of April 21 The wet zone to the south of the Great Wall of China provides a suitable habitat for *Gentiana stylophora*, *G gilvostriata*, *G setulifolia* and others, whilst the dry regions to the north of the Great Wall have other species There is a further subdivision of the dry parts into forest and grassland, each with its own gentian flora, though some species are very widely distributed The notes also include descriptions of several gentians introduced by Capt Kingdon Ward from Tibet last year *G Waltonii*, *G Georgii*, *G trichotoma*, *G filistyla*, *G Wardii*, *G sino ornata* and *G detonsa* are described, in addition to the three mentioned above The Lhagu gentian, a mat forming species, was found among the grassy slopes of the snow range at 14,000 ft , and promises to be a delightful plant if it can be introduced to cultivation

Geography of Earthquakes In a long article in *Matériaux pour l Etude des Calamités* (No 30–31, 1933) entitled Die Anthropogeographische Bedeutung der Erdbeben", Dr W Severit gives a useful summary of the geographical distribution of earthquakes in recent times with special reference to the more destructive ones A map shows the number of shocks during the last century This part of the memoir is followed by a discussion of the effects on soil, drainage, climate, human distribution and the works of man Finally, there is a study of the measures of prediction, security and relief The whole is well documented, and may usefully serve as an introduction to the subject

Wind Structure As a result of the special inquiry into wind structure that was carried out at Cardington a few years ago, by the Airship Services Division of the Meteorological Office, Mr C S Durst formed a novel theory of wind structure that explains many features shown on continuous records of the speed and direction of the wind such as those obtainable with the aid of the Dines' pressure tube anemometer In addition to the rapid and irregular fluctuations of speed and direction that are regarded as the result of irregular eddies with axes inclined in all directions, caused apparently by the striking of air against obstacles, Durst found large excursions of the speed and direction pens, generally lasting 1–30 minutes and showing as a rule a rapid initial increase of speed followed by a gradual decrease accompanied by increasing small disturbances of the frictional type just described There was abundant evidence that the initial squall corresponded with the arrival of faster moving air from a higher level, and that the whole phenomenon up to the beginning of another sudden increase of speed was associated with a local convectional circulation which he termed a 'cell', this circulation being superimposed on the general drift of the wind Mr Durst has recently discussed the anemograms from a number of places with anemometers having widely different exposures from this point of view (*Quart J Roy Met Soc* , Oct 1933) It is found that over the sea the frictional eddies are better developed in air of equatorial origin than in polar air, doubtless because the increase of wind with height is greater in the equatorial air, but that, given sufficient vertical stability in equatorial air over the sea, smooth flowing air can persist with higher speeds there than over agricultural land

Acuity of Vision Kruysuyk and Zwikker (*Physica*, 1, 4, Feb 1934) have published an account of experiments in which the acuity of vision was tested at different intensities of illumination, using as a criterion the recognition of small solid objects These were placed in effect at variable distances from the observer The acuity of vision was tested for several observers in white and in monochromatic sodium light The curves connecting intensity of light with acuity of vision slope upwards, following roughly a ½ power law, and show in general a bending over (saturation effect) at high light intensities, but this effect is much more marked for some of the test objects than for others For the lower intensities of illumination, the acuity at given intensity is much better for sodium light than for white light, but they tend toward the same saturation value The acuity is considerably greater and the effort of discrimination is less for two-eyed than for one eyed seeing

Valve Amplification at Radio-Frequencies A paper published by Mr F M Colebrook in the *Journal of the Institution of Electrical Engineers* of February 1934 discusses the relative merits of screen grid valves and three-electrode valves for amplification at frequencies of the order of a million cycles per second Voltage amplification by means of tuned circuits and screen grid valves is limited by conditions of stability and by the curvature of the amplification characteristic In the reception of broadcasting in particular, this curvature of the characteristic may lead to a reduction in apparent selectivity due to cross modulation, and an increase in background noise This effect is illustrated in the paper by typical measured amplification characteristics An analysis of a triode amplifying stage shows the possibility of securing inherently stable tuned circuit amplification by using a buffer valve stage to minimise the effects of the input impedance of the amplifying valve A measurement of such a stage at a frequency of a million cycles per second gave results in agreement with theory and showed that an output of about 100 volts could be obtained without appreciable curvature of the amplification characteristic Thus, although the three electrode amplifying circuit may not be preferable to the screen grid stage in all cases, it should facilitate reception at large power output with a minimum of audio frequency amplification With this object in view, special emphasis is laid in the paper on the desirability of making a simple modification to the design of the standard receiving triode in order to reduce the capacitance between the grid and anode.

Emission of Electrons in Chemical Reaction Denisoff and O W Richardson have published (*Proc Roy Soc*, A, March) a further instalment of the work on the emission of electrons when gases at low pressure react with sodium potassium alloy A refined re investigation of the reaction with phosgene has been made in order to determine the energy spectrum of the emitted electrons with considerable accuracy The paper summarises the general conclusions reached by these and by the former experiments—it is found that the energy distribution is not Maxwellian, as was formerly suspected, but that the distribution curve rises to a maximum at a certain energy and falls nearly to zero at a certain maximum energy, E_m Beyond this there is a very small tail, like that observed for the photoelectric effect For the chlorine compounds studied, $E_m + D$ is a constant where D is the dissociation energy of the compound The authors account for the distribution by supposing that the reaction between the metal atom and a chlorine atom to form a polar bond may be effected by a three body collision in which a metallic conduction electron carries off the surplus energy of the reaction The maximum energy E_m is thus the chemical reaction energy diminished by the work function of the metal This result appears to agree with experiment

Hydrazoic Acid Most of the reactions of hydrazoic acid, HN_3, support the conclusion that it is an ammono nitric acid

$$HONO_2 + 2NH_3 = H-N=N\equiv N + 3H_2O$$

(Franklin, *J Amer Chem Soc* March 1934) The potassium salt can be obtained by the reaction

$$KONO_2 + 3KNH_2 = KN=N\equiv N + 3KOH + NH_3$$

The action of the acid on metals is in many ways analogous to that of nitric (aquonitric) acid the evolution of hydrogen reported by previous experimenters does not occur with zinc, iron, manganese, nickel and copper, the products being the metallic azides, nitrogen (previously mistaken for hydrogen), and ammonia with small amounts of hydrazine, with magnesium (which also gives hydrogen with very dilute nitric acid), some hydrogen is also evolved A mechanism of reduction of the hydrazoic acid is suggested Hydrazoic acid does not dissolve gold, it will do so (as well as platinum) if mixed with hydrochloric acid, and the aqua regia" heated with the metal The mixture of acids also slowly evolves chlorine on boiling Ferrous azide is converted into ferric azide when heated with excess of hydrazoic acid, hydrogen sulphide is nitridised' (rather than oxidised') to sulphur, and sulphur to sulphuric acid by hydrazoic acid, and a stannous salt can be converted into a stannic salt by a fusion reaction with sodium azide Several organic reactions are also in agreement with this structure It may be mentioned that there is physical and physico chemical evidence besides the chemical evidence given in Franklin's paper, that hydrazoic acid and its salts have not the ring structure often given but a linear structure $H-N=N\equiv N$ or more strictly, $H-N=N\overset{\rightarrow}{-}N$, as proposed originally by Thiele

Stellar Photometry in the Infra-Red A new type of photoelectric photometer employing a cæsium oxide cell, has been described by J S Hall (*Astrophys J*, 79, 145) It is only possible to use this type of cell for stellar photometry if it is cooled to about −40° C by means of solid carbon dioxide, in order to reduce the dark current', or current which flows when no light strikes the cathode The colour curve of such a cell shows great sensitivity in the infra red, and intensity measurements may be made at well separated effective wave lengths A detailed description of the apparatus is given, as used in conjunction with the Loomis cœlostat telescope of the Yale Observatory The Pleiades were used for calibration purposes, and colour observations made on 347 stars and on the variable star ζ Geminorum The phases in the light curve of this variable as observed in the infra red are later than those observed in the visual, corresponding to the previously noticed phase difference between observations in the visual and the blue regions An interesting suggestion is made as to the possibility of finding the absolute magnitudes of giant stars of later spectral types from accurately measured colour excesses, observed in this manner in the infra red

Dipole Moments and their Interpretation

FEW branches of physical chemistry can show a more rapid development than the study of dipole moments. The theoretical work of Debye goes back to a discussion of the Mosotti-Clausius equation in 1912, but the experimental work really begins with Zahn's measurements on gases in 1924 and the work of Smyth, Williams and others on solutions a few years later. To-day, values of the dipole moment have been determined for more than a thousand substances, and measurements of dielectric properties are applied to such varied topics as the determination of valency angles, the size of colloid molecules, and the order of the boiling points of isomeric substances. It is not surprising therefore that the discussion on 'The Determination and Interpretation of Dipole Moments' held by the Faraday Society at Oxford on April 12–14 attracted a large number of British and foreign workers in this field. The outstanding figure was, of course, that of Debye; those who attended the meeting will long remember his shrewd comments on every paper, his genial smile and his cigar which served so aptly as a model of a dipole.

It is only possible to mention a few of the many papers which were read. The first group was concerned with the determination of electric moments of molecules. It seems to be generally agreed that atomic polarisations are small and are rarely greater than 5 c.c. Anomalous dipole moments can now no longer be ascribed to large values of P_A. On the other hand, the work of Horst Muller, Jenkins and others shows clearly that the magnitude of the dipole moment deduced from measurements in solution is influenced by the dielectric constant of the solvent. A number of formulæ connecting measured polarisation and dielectric constant were discussed, but much more work on vapours as well as on solutions is needed before the solvent effect can be accurately determined.

Debye's opening paper contained an account of novel work by Martin on dielectric losses in dilute solutions of a polar substance in a non-polar solvent. Following Malsch, the thermal expansion of the solution was used as a delicate method of measuring the heat developed by absorption of electrical energy. Non-polar substances gave negligible heating but polar substances showed a marked effect. Thus with 0·1 molecular solutions of orthodichlorobenzene ($\mu = 2·25$D*) and paradichlorobenzene ($\mu = 0$), the relative heating effects were in the ratio 310 : 1. Theory indicates that the effect should be proportional to the square of the dipole moment μ, and from the measured energy absorption the relaxation time of the polar molecule can be computed. In accordance with elementary theory, this is found to be of the order of 10^{-11} seconds for solutions in solvents of low viscosity, such as benzene. The elementary theory assumes spherical molecules and Stokes's law, and the experimental data diverge considerably from the predicted results. It seems probable that further investigations along these lines may give information about the shapes of molecules.

Determinations of relaxation time from measurements of anomalous dispersion at high radio frequencies were discussed in the papers contributed by Williams and by Girard. The latter finds anomalies in the shape of the dispersion curve for glycerol which he ascribes to the presence of two species of molecules, namely, normal and associated molecules. Girard also notes some curious empirical relations between the dielectric properties of hydroxyl compounds. Thus for the normal aliphatic alcohols from propyl alcohol upwards, the product of the molecular weight and the dielectric constant at 20° C. is nearly constant.

Another group of papers was concerned with the problem of free rotation. There is, of course, a mass of chemical evidence in favour of free rotation about a single bond. More accurately, it should be said that if isomerides exist which differ in structure merely by the relative angular orientation of groups about a single bond, then these isomerides are so readily interconvertible that they cannot be isolated. Dipole moments give a good deal more information about such rotations. Thus the existence of a dipole moment for hydroquinone dimethyl ether is explained by the rotation of the $-$OMe groups about the C$-$O bond. Williams and others have discussed molecules of the type of ethylene dichloride and distinguished three extreme cases: (*a*) the repulsions between the chlorine atoms fixes them in the *trans* position giving $\mu = 0$, (*b*) the chlorine atoms are fixed in the *cis* position and $\mu = 3·6$D, (*c*) the CH_2Cl groups rotate freely about the C$-$C axis with all orientations equally probable and $\mu = 2·5$D. Zahn has measured the dipole moment of ethylene dichloride in the vapour state and finds that it varies with temperature from 1·12D at 32° C. to 1·54D at 281° C. This is interpreted as indicating that the *trans* position is the most stable, and that increasing *thermal vibrations give oscillations from this position*. The problem is, however, one which deals with phenomena on the atomic scale and can only be solved satisfactorily by the methods of wave mechanics. An illuminating discussion of the restriction of free rotation in molecules of the type XCH_2CH_2X was given by Lennard-Jones. From suitable molecular models a wave equation was set up and an equation obtained which accounts quantitatively for the change of dipole moment with temperature.

Another interesting quantum discussion of a similar problem was given by Penney and Sutherland on the structure of hydrogen peroxide and hydrazine. These molecules give unexpectedly large dipole moments, which have been ascribed to free *rotation. An examination of the problem by quantum* mechanical methods shows that the main forces determining the structure of the molecule are not the electrostatic repulsion between the terminal hydrogen atoms but the interaction between the electron clouds associated with the oxygen atoms in HOOH and the nitrogen atoms in H_2NNH_2. The most stable configuration for hydrogen peroxide is a skew one in which the planes through the O$-$O axis and the H atoms are nearly at right angles. In other words, the most stable position is about halfway between the *cis* and *trans* positions. A similar structure is found for hydrazine; for both substances the observed dipole moments are in fair agreement with the values calculated for the skew configuration.

---

* D is the Debye unit, 10^{-18} E.S.U. C.G.S.

A group of papers was devoted to the discussion of resonance phenomena Here one is concerned primarily with the rapid oscillation of electrons between different positions in the molecule, and not with the movements of nuclei as in the free rotation problem The problem of the structure of the organic azides was discussed by Sidgwick The azido ion has undoubtedly the linear structure N=N=N, for the covalent organic azides three structures are possible as shown below Parachor and volatility favour I, whilst chemical reactions, electron diffraction, and recent crystal structure measurements reported by Bernal indicate a linear structure, II or III The dipole moments of a number of azides give for the moment of the Ph–N_3 group about 1 5D This is scarcely larger than the moment of the Ph N group, so that the links in the N_3 group contribute very little to the moment II and III should give large contributions in the senses indicated by the arrows below the formulæ, so the dipole moments seem to favour structure I This is, however quite incompatible with the electron diffraction and crystal measurements

I

II

III

The low moment cannot be reconciled with a linear arrangement of the nitrogen atoms by postulating tautomerism in the chemical sense of the word between forms II and III If the time of interchange between the two forms is less than the relaxation time (c 10^{-11} sec), then each form would orient under the influence of the applied field and the observed moment would be large although the two forms have moments of opposite sign Quantum mechanical resonance between the two forms with an interchange time of the order of 10^{-15} sec would account for the observed moment For this to occur it is necessary for the two forms to have equal or nearly energies Sidgwick has computed the heats of formation of the N_3 group making certain plausible assumptions with the following results

I, 170 k cal II, 191 k cal III, 180 k cal

The observed value calculated from the heats of combustion of organic azides is 211 k cal This seems to exclude I and is compatible with resonance between II and III, since resonance increases the stability of the molecule and would increase the heat of formation

The vector addition of dipole moments and the calculation of valency angles were considered in another group of papers The chief difficulty met with in this field is the uncertain magnitude of the interaction between two dipoles in a molecule or between a dipole and the polarisable part of the same molecule Hampson described a method of eliminating such errors considering the moments of a series of compounds, for example

where X is a group of known moment From the three measured moments it is possible to fix upper and lower limits for the valency angle and to estimate the magnitude of the perturbing induced dipole along the X O axis For the oxygen valency angle consistent values of about 130° were found, the induced dipole was small when X was Cl but when X was NO_2 amounted to half a Debye unit

Finally mention must be made of the remarkable results found by Hassel for certain cyclohexane derivatives 1 4 dichloro, dibromo and di iodo cyclohexane were found to have zero moment in solution in benzene This result is not easily reconciled with the usual view that cyclohexane derivatives consist of a tautomeric mixture of two strainless forms with a non planar configuration

S S

University Statistics of Great Britain

UNIVERSITY statistics of Great Britain for the year 1932–33, recently issued by the University Grants Committee*, show that the attendance of students has been well maintained and university finances have a healthy appearance It would seem that the measures taken to temper the effect on universities in Great Britain of the inclement economic weather prevailing in the past few years have achieved their object The enrolment of full time students has been gradually rising since 1924–25 and showed last year a further increase of 1 255—1,267 more men and 12 fewer women Of the aggregate total of 50,155, five per cent were engaged in research and other advanced work, seventy seven per cent were reading for a first degree and eighteen per cent for a diploma Part time students numbered 13,960, of whom rather more than half were not pursuing regular courses leading to a degree or diploma

A regional distribution of the full time students gives to London, 24 per cent, Oxford and Cambridge, 21 per cent, provincial universities of the Midlands and northern England, 21½ per cent, Reading, Southampton, Exeter and Bristol, 5 per cent; Wales 6½ per cent, and Scotland, 22 per cent

Students from abroad, that is, from homes outside the British Isles, numbered 5,870—about one tenth of the total number—considerably more than half of them being from countries within the British Empire these show, however, a tendency to decrease in proportion to those from foreign countries The following table gives particulars in respect of universities where such visitors from abroad were most numerous, showing (1) full time students from places outside the British Isles but within the Empire, (2) those from foreign countries, and (3) the percentage of (1) plus (2) to the total number of students

---

* University Grants Committee Returns from Universities and University Colleges in receipt of Treasury Grant Academic Year 1932–33 Pp 26 (London H M Stationery Office 1934) 1s 3d net

	Students from abroad		(Per cent)
	(1)	(2)	(3)
London	1 191	674	16
Sch of Economics	141	234	39
Imperial College	163	50	20
University Coll	221	118	17
Guy's Hospital	99	18	14
St Bart s Hospl	78	34	15
Oxford	290	234	11
Cambridge	346	192	9
Birmingham	28	85	11
Edinburgh	329	176	14
St Andrews	14	87	11

In view of current controversies and world wide perplexity in regard to economic doctrine, it is noteworthy that the London School of Economics draws so many students from abroad

Analysis according to subjects of study reveals a substantial increase of 807 (eight per cent) in the number of medical students and a falling off of five per cent under agriculture

University finances, which are to a large extent dominated by State aid—parliamentary and local authorities' grants together amounting to 44½ per cent of the aggregate of university incomes—have called for close and unremitting attention on the part of university administrative authorities since the national financial crisis of 1931 Evidence of the effectiveness of their control is to be found in the fact that there were only four institutions the accounts of which showed deficits on the year and in only one was the deficit of any substantial amount The aggregate amount of debt on capital account at the close of the year was about one million pounds, or one sixth of the aggregate annual income

Expenditure on libraries is dissected in a special table which shows that of the total, £210,756, sixteen per cent was on account of purchase of periodicals, the increasing number and cost of which was already three years ago, when they were responsible for little more than ten per cent of library expenditure a source of embarrassment

Four London institutions now make their first appearance in the returns the Courtauld Institute of Art first opened in October, 1932, the Institute of Education (formerly the London Day Training College) transferred from the control of the London County Council to that of the University of London in September, 1932, the Institute of Historical Research statistics of which were previously not differentiated in the returns from those of the University of London as a whole, and the School of Slavonic and East European Studies transferred from King s College to the University of London in August 1932

Quantitative Methods of Biological Assay

THERAPEUTIC substances which cannot yet be completely defined by their physical and chemical characteristics, can only be used with safety when their activity has been determined by tests on animals The accuracy of such tests has been greatly increased during the last decade especially since it was realised that large numbers of animals must be used in each assay so that the average response of a group of animals can be determined, allowance thus being made for the differences in response of the individual animals Such tests may be of two types either the response of each animal to the drug is accurately measured, for example, the effect of insulin upon the blood sugar of the rabbit, or observation is only made as to whether some specific effect is produced or not for example, the effect of insulin upon the mouse, when the end point is the occurrence, or not, of convulsions Gaddum has recently made an analysis of the latter type of test and his report should be of great value in the interpretation of the results of such experiments *

In tests of the all or none' or 'quantal' type it is now usual to inject several doses of the substance under test into a series of animals ten or twenty or more being used for each dose, and to plot the percentage number responding on each dose against the dose given The curve which is then drawn to pass approximately through the plotted points is *S* shaped, the shape and slope of the curve being characteristic for each combination of drug and test animal species It is often more convenient to plot the effect of the drug against the logarithm of the dose (to base 10) instead of against the dose itself, the characteristic curves are then easier to interpret The most satisfactory index of the slope of the curve, and so of the uniformity of the animals, is the standard deviation of the logarithms of the individual effective doses, which can be estimated with sufficient accuracy by taking from the curve the log dose corresponding to 84 per cent subtracting from it the log dose corresponding to 16 per cent and halving the result

Gaddum also recommends that instead of using the percentage of responses on each dose as a measure of the effect the normal equivalent deviation be plotted against the logarithm of the dose, since this function gives a more satisfactory measure of the effect than the percentage does It is equal to the deviation from the mean, and is obtained in practice from tables When the normal equivalent deviations are plotted against the logarithms of the doses the points so obtained lie approximately on straight lines, when the logarithms of the individual effective doses are normally distributed It is therefore usually sufficient to use only two doses and to take the line joining them as an indication of the relation between the logarithm of the dose and the effect This line is completely described by calculating the dose which produces the effect in half the animals and the standard deviation of the logarithms of the individual effective doses

The report is illustrated by a number of curves obtained by different observers in assays of different drugs or hormones such as ouabain neoarsphenamine, oestrin and pneumococcus antibody The control of variables which affect the homogeneity of the animals used, such as their genetic composition, weight, age, sex, diet and environmental temperature, is also discussed The mathematical argument involved in the use of these curves is described and, in greater detail the methods of carrying out a test, two examples being included

University and Educational Intelligence

CAMBRIDGE —It has been recommended that one University lectureship in forestry be transferred from the Faculty of Agriculture to the Department of Botany, and that the lectureship be called the University lectureship in forest botany

LONDON —The following appointments have recently been made · Capt G T R Hill to the Kennedy chair of engineering (University College), Dr L P Garrod to the University readership in bacteriology (St Bartholomew's Hospital Medical College), Dr G R Cameron to the University readership in morbid anatomy (University College Hospital Medical School), Mr. John D Cowley to the directorship of the University School of Librarianship at University College

The Dunn exhibitions in anatomy and physiology for 1934 have been awarded respectively to Mr Alfred Cohen (University College) and Mr A J Bernfeld (Middlesex Hospital Medical School)

WALES —University College, Cardiff, has received a further gift of £1,000 from the Rothschild residuary fund It has been decided to expend the greater part of the sum on library purposes

Sir Howell Williams, of Corris, Merioneth, has promised £10,000 for the new college building scheme of the University College at Aberystwyth This scheme is estimated to cost £500,000 Lady Gladstone of Hawarden has offered to endow two Rendel Memorial Scholarships as a memorial to the late Lord Rendel

The University College of North Wales at Bangor celebrates its jubilee this year

---

HISTORY and geography teaching, considered in relation to the problems of 'moral disarmament', is dealt with in several papers published in the December issue of the League of Nations' *Educational Survey* There is, first, the full text of a lecture by M Maurette, assistant director of the International Labour Office, giving a vivid presentation of methods whereby history and geography teaching in primary and secondary schools may help their pupils to grow up "to realise the only hope for the salvation of man on earth and the law which must govern the inhabitants of a globe whose limits are shrinking daily and whose different parts are becoming increasingly members one of another" It is followed by two authoritative *communiqués* concluding an acrimonious debate provoked by an article which appeared in a previous issue of the *Survey* The position of the writer of the article, Mrs Corbett Ashby, as a delegate at the Disarmament Conference necessarily aggravated the seriousness of her accusations that "national and racial animosity are inculcated by teachers in obedience to false ideals of morality" A communication from Dr C W Kimmins includes a memorandum by Dr C B Firth on the general characteristics of the way in which children are now encouraged to learn history in English schools, and emphasises that for the last twenty years the kind of geography taught in the majority of schools in England has been equally unlike anything that Mrs Ashby described and rightly condemned.

Science News a Century Ago

"Great Points in Electricity"

In 1834 Faraday was approaching the end of the electro chemical researches which had occupied him for the previous two years His paper on the 'Electricity of the Voltaic Pile" was read before the Royal Society in June of that year, and a few days earlier, on May 29, he wrote in his Diary a short passage which gives an interesting indication of his ideas on electrolytic conduction at the time He hoped that electrolysis might afford a means of distinguishing between elementary and compound bodies

The passage, which is headed "Great Points in Electricity which require to be decided", shows that he had grown accustomed to using the new word ion' 'Is not the existence of compound *ions* assumed rather than proved? Has an acid or a base yet been determined to the electrodes except in a solution, and would they go in equivalent proportions in ordny salt? In fact is it not the simple bodies only which truly and freely traverse? This not yet definitely decided "

'If there are, still, may we not by Electrical relations of the simple *ions* distinguish between real elements and such as we may think to be such because we have not decomposed them? That is, will not electricity prove to be the test between bodies really simple and those which are compound? If so, probably our present elements are true and ultimate elements "

Death of Laumont

On June 1, 1834, the French mineralogist, François Pierre Nicholas Gillet de Laumont, died in Paris Born on May 28, 1747, he was educated at a military school and served in the army from 1772 until 1784 He was then appointed an inspector of mines and devoted his leisure to the study of mineralogy He wrote many papers for the *Annales des Mines* and assisted in organising the Paris School of Mines The mineral laumontite was named after him by Hauy

London and Birmingham Railway

On June 1, 1834, at Chalk Farm, the first sod was cut for the London and Birmingham Railway, the first main trunk line in Great Britain The royal assent to the bill for its construction had been obtained on May 6, 1833, after a Parliamentary struggle which had cost the promoters of the line £72,869 Robert Stephenson, then thirty years of age, had carried out the surveys for the line, and though there was much opposition, the directors on September 7, 1833, resolved "That Mr Robert Stephenson be appointed engineer in chief for the whole line at a salary of £1,500 per annum, and an addition of £200 per annum to cover all contingent expenses, subject to the rules and regulations for the engineers' department, as approved by the respective committees" Fixing his residence in St John's Wood, and with the Eyre Arms Hotel as his office, Stephenson reserved for his own personal supervision a length of about nine miles from Maiden Lane, Camden Town, and divided the remaining 103 miles into four districts, each under an assistant engineer The actual construction of the line was entrusted to about twenty contractors, but the completion of some of the most difficult portions had to be superintended by Stephenson *himself* The work of the greatest magnitude was the construction of the Kilsby Tunnel south of Rugby, a costly undertaking rendered necessary through the short sighted opposition of the inhabitants of Northampton to the proposal that the line should pass by way of that town

John Dalton

Dalton was elected a fellow of the Royal Society in 1822, and received one of the Society's Royal Medals in 1826, the first year of award, but until May 1834, he had not attended to be formally admitted Babbage was, at the time, actively interesting himself in Dalton's presentation at Court, duly effected, it may be mentioned, though he did not go clad in levée dress The particular reason, however, for Dalton's stay in London was to give sittings to Chantrey, the sculptor, who had been commissioned by a representative committee to execute a statue of him Dalton recorded his visit to Chantrey thus He [Chantrey] took a profile as large as life by a camera lucida, and then sketched a front view of the face on paper He then gave me the next day for a holiday and told me I should see my head moulded in clay on Wednesday morning, at which time he invited me to breakfast I went accordingly and found, as he said, a head *apparently* perfect He said he had not yet touched it, the head having been formed from his drawings by some of his assistants He set to work to model and polish a little whilst I was mostly engaged in reading the newspaper, or conversing with him On looking right and left he found my ears were not alike, and the modeller had made them alike, so that he immediately cut off the left ear of the bust and made a new one more resembling the original At last he took a pitcher and blew a little water in my face (I mean the model), and covered my head with a wet cloth and we parted, he having desired me to bring Dr Henry and Dr Philip with me next morning to breakfast We went accordingly and found an abundant table, soon after Dr Faraday came in and we all went into the working room for a time At intervals we have a little amusement and instruction about our respective arts and sciences, and how we acquired our knowledge, etc, in which we vie with each other' (Henry, "Memoirs of John Dalton", 1854)

Sir Henry Holland in his 'Recollections" (p 212) remarks, referring to Dalton's early years, that he well knew that philosopher in his rude laboratory of bottles and uncouth apparatus at Manchester—an individuality in himself, apart from the Quaker garb he wore "

Wernerian Natural History Society, Edinburgh

In May 1834 the Society promoted and offered a number of honorary premiums, open unconditionally to all scientific workers The terms were incorporated in a circular notice, from which three examples are quoted —

(1) Twenty sovereigns, or a suitable piece of plate of that value for the best geological account, with a geognostical map, sections, and specimens, of the Three Lowthians, with as much of the neighbourhood as may be required for the elucidation of the districts To be given in against December 1835

(2) Ten sovereigns, or a piece of plate for the best natural and economical history of the fishes, marine, fluviatile, and lacustrine of the river district of the Forth To be given in against December 1835

(3) Ten sovereigns, or a piece of plate for the best account of the entomology of the Three Lothians, and river district of the Forth, with a collection of specimens, and map of the distribution of the insects To be produced against December 1836 (Memoirs, vol 7)

Societies and Academies

London

Physical Society, March 16 N Thompson The effective rotation temperature of the negative glow in nitrogen The effective temperature increases slightly with the pressure and current strength, and to a much greater extent with the temperature of the furnace surrounding the discharge tube At high temperatures it becomes less than the temperature of the furnace, and an explanation of this surprising behaviour is sought It is concluded that, in this particular case at least, the effective temperature is not identical with the gas temperature, though it depends in part on that quantity S S Watts and B J Lloyd Evans The measurement of flame temperatures in a petrol engine by the spectral line reversal method Until recently no satisfactory method existed for the measurement of the temperatures during combustion in a petrol engine The reversal of a spectral line provides a suitable method which shows that the maximum temperature in the engine cylinder persists for a longer period than the maximum pressure E B Moss An apparatus for the determination of the dew point The paper describes an optical system which uses diffraction by the dew droplets on a mirror and aids greatly the visual detection of dew formation Then follows an account of the application of this system to an automatic photoelectric apparatus for maintaining a mirror at the dew point

Dublin

Royal Irish Academy, April 9 R Southern Food and growth of brown trout in Lough Derg and the River Shannon The growth rate and size of the trout is definitely correlated with the composition of the rocks in the drainage area The water of Lough Derg and the Shannon is derived from limestone rocks and is alkaline, that of Lough Atorick comes from an area of Old Red Sandstone and peat and is acid The trout from Lough Derg and the River Shannon are large, quick growing, have a relatively long life and mature late Those from Lough Atorick are small, slow growing, have a short life and mature at an early age In the diet of the Lough Derg trout, 'mid water' food, consisting of *Cladocera* of the plankton and perch fry, forms a considerable part, but the Lough Atorick trout do not utilise this abundant food and live to a large extent on terrestrial insects blown on to the water The Shannon trout subsists almost entirely on bottom living organisms

Leeds

Philosophical and Literary Society, March 6 A Y Amin Note on a property of *Steinerian trihedra* H Frazer Subharmonic functions The author generalises the various results he has given recently concerning subharmonic functions R Whiddington E G Woodroofe and J E Taylor Note on the excitation of the neon atom by electron impact The changes of energy of the neon atom when bombarded by electrons of 120 volts are considered Three transitions from the ground state 2^1S_0 to the $3s$, $3p$, $3s_1$ states are observed The energy changes agree with those expected spectroscopically and the probabilities of the excitations are approximately in the ratio 16 4 5 J E Roberts Excitation of the nitrogen molecule by electron impact A brief survey is made of the question of the excitation of *diatomic molecules by electrons from the normal* to higher electronic states and two problems arise (*a*) the most probable energy loss of the exciting electron and (*b*) the probability of excitation of vibrational levels near to the most probable levels The case of the $X \rightarrow a$ transition in nitrogen is considered in detail The best available potential energy curves are obtained using the known spectroscopic data and the Morse formula Assuming harmonic vibration of the nuclei the relative probabilities of excitation of a few of the vibration levels of the *a* state are calculated These are in good agreement with the experimental results of Brindley though the most probable energy loss found by Rudberg is somewhat higher H M Dawson and W Lowson Velocity of the reaction between sodium chloroacetate and sodium hydroxide Measurements at 25° with the chloroacetate in considerable excess (1M $CH_2Cl\,CO_2Na$ + 0 1M NaOH) show that the bimolecular velocity coefficient remains sensibly constant until about 70 per cent of the alkali has disappeared but increases continuously in the later stages of the reaction This increase appears to be due to the simultaneous occurrence of three other reactions in which the products of hydrolysis are formed as a result of the interaction of the chloroacetate ion with water molecules other chloroacetate ions and glycollate ions respectively W Cameron Walker A portrait of Joseph Priestley and some of its associations E Marjorie Wray Structural changes in a woody twig after summer pruning The basipetal development of the cambium and the dependence of radial growth upon the developing bud results in the isolation of any part of the stem left above the topmost bud as a result of pruning as a snag This explains the pruning instruction always given, to prune immediately above a bud The rapid drying of the snag is very unfavourable to meristematic activity and the only evidence of cambial activity in the snag is the formation of cork phellogen round the schlerenchyma and also just within the protoxylem The healing of a well pruned stem is so complete that in a year or two the cut is almost obliterated and thus entry of disease is prevented Late summer pruning is followed almost immediately by the outgrowth of a single bud This is attributed to the fact that at this time of the year, when the water table in the tree is low and the air temperature is high, there is only sufficient water available to force one bud into growth

Milk Supply in Relation to National Health

THE milk supply of Great Britain is engaging—as indeed it should—a large and increasing measure of public attention The difficulty of securing a remunerative price for milk is vexing more and more the minds of dairy farmers and of all who hold that a prosperous agriculture is *the corner stone of an enduring edifice of national* prosperity Prominent members of the House of Commons animated by a desire to increase the consumption of milk and to improve the health of the people are advocating that all children in State aided schools should receive a daily ration of milk Many of the medical profession whilst strongly in favour of this and other proposals designed to promote the drinking of more milk insist as guardians of the public health that milk must be *pasteurised* The recently formed Milk Board is preparing to engage in a campaign in which all the [illegible] of publicity will be used to promote the milk drinking habit and to these present and prospective efforts the *Times* is lending public spirited and invaluable support by opening its columns generously to correspondence from all quarters

The Committee of the Economic Council the appointment of which some time ago is proof of the Government s deep concern in questions relating to milk supply and consumption has completed its labours and its report will doubtless increase yet more public interest in a subject of which it is not possible to exaggerate the importance The moment is therefore opportune for a consideration of the problem of the national milk supply from a biological point of view

This consideration is to be justified on the ground that apart from its political and economic aspects the national milk supply is in its essentials, a biological problem At the very root of it lies the question how to secure to the nation a copious and constant supply of milk of the highest possible quality ?

The biologist will regard it as self evident that the health and strength of mankind depend more on milk than on any other nutrient agent whatsoever more perhaps than on all the other agents put together In milk health and strength have their origin and sustenance To this conviction all the new and rapidly accumulating knowledge of the many and decisive parts played by vitamins and by minerals in promoting growth and maintaining health lend unequivocal support It does more The new knowledge brings a new hope to the world The new-born hope sees the vitamins, the children of light, fully engaged in the service of man They prevail against the children of darkness The microbes that make so many maladies are vanquished one by one Mankind rejoices in an ever growing freedom from disease The new knowledge brings also as its first fruits a salutary uncertainty to science It is a new wine that will burst many old bottles The whole science of nutrition will have to be reconstructed on the basis of this knowledge, and the first step toward reconstruction must be a re investigation of the nutritive value of milk

At present no one knows how great that value is The mystical opinion is prevalent that milk is a composite principle an embodiment of good and evil It will be discovered presently how to make it wholly good The current opinion may be due to a simple cause Experiments carried out before it was possible to make a physiological analysis of milk—and it is even now not yet possible to make a perfect analysis of it—led often to conclusions which cannot be accepted as final because of the uncertainty of the composition of the milk with which they were made For, like Cleopatra, milk is of infinite variety It may be rich or it may be poor in health giving properties, and so all the old experiments which seemed so conclusive must be redone with material of known and high quality

Summer milk from cows grazed on pastures of young grass—the sweetest thing that grows—is rich in vitamin A and its precursor, carotene It has a comforting and agreeable flavour There is life in it Winter comes Growth of grass declines as the sun declines The lowing herd winds from the pasture to the byre Natural food gets scantier As winter pursues its sunless tedious course the vitamin A and carotene in the milk from the stall fed kine get progressively less, not to increase again until spring comes, and with the resurrection of the life of the pastures the dairy herd goes back to Nature for its food Can it be doubted that other equally and even more important seasonal variations in the composition and virtue of milk still await discovery seasonal variations in the amount of available bone building lime, of phosphates, iodine, other minerals and other vitamins! May not these seasonal deficiencies be the ultimate cumulative cause, generation after generation, of malnutrition and disease? They come at a time when their effects are doubly disastrous, in winter, when the sun itself grows pale and leaves health least fortified against attack

If, however, these things are true of the children who drink the milk, they must be true no less of the cow that makes it Like the pelican she gives her life's blood to feed the young In summer the sacrifice is light, but in winter how severe! May not bovine tuberculosis and other of the diseases which affect dairy herds be but the belated consequences of seasonal deficiencies of nutrition imposed by climate upon cattle? In the lowered state of resistance, pathogenic micro-organisms find their occasion, and a symptom of malnutrition comes to be regarded as a cause of disease 'Where the carcase is the eagles will be gathered together"

It is said that tuberculosis is rare or non-existent among cows of the Jersey breed so long as they stay in that fortunate island, but that when they go elsewhere they leave their immunity behind them If this be so, must not the resistance and susceptibility alike have their origin in nutrition? In the longer grazing season and in their fuller access to food from well managed pastures the cows find strength, but in a shorter season of less nutritive pastures they lose it, and in losing it become a prey to disease Whether the example be well founded in fact or not this at all events is indisputable the task of securing the best possible milk for the nation must be begun at the source—England's green and pleasant land, the green pastures Jerusalem, if ever to be builded here, must be built on them A defectively nourished people will never build it No man who travels in autumn time from the radiant valleys of Savoy to the sullen highlands of Auvergne will ever doubt again that health and happiness come to mankind by a tortuous route from heaven via the earth

The cultivation and management of pastures must serve as the basis on which a copious and consistent supply of rich milk must be established Those pastures can be made to yield all things necessary to health and strength The cows that graze them will give milk excellent in quality and delicious in flavour, a flavour which children will be eager to enjoy

The pleasant taste of milk and butter from cows fed on rich pastures is bound up with the presence of vitamin A and carotene, as though Nature were trying to coax the children of mankind to feed on what is good for them If therefore young England is to become a confirmed and heavy drinker of milk, palatability must be taken into consideration. For in this as in most matters the child has the last cry. Few mothers and fewer fathers dare impose their will on a reluctant babe.

This apparently trivial but really essential aspect of the subject bears on the problem of pasteurisation a thorny subject. The biologist who approaches it finds himself like Issachar "a strong ass couching down between two burdens". On one side is the weight of his respect for medical opinion on the other, the uneasy load of his belief that raw milk of high quality will prove superior to pasteurised milk. Accustomed to compromise by the baffling complexity of the phenomena with which he habitually deals, the biologist would accept pasteurisation of milk open to suspicion as a provisional and precautionary measure, provided that any enforcement of it were recognised explicitly as no more than precautionary and provisional. Nor would insistence on the safeguarding clause be dictated solely by doubt. It would also be inspired by the belief that search for other ways of preventing the carriage of pathogenic micro organisms by milk would find better ones.

Finally, the biologist cares not at all if the views which have been expressed find little acceptance so long as what is implicit in the argument is made to take immediate effect. It is that a great national effort must be made to discover means of securing to the people all the year round, plentiful supplies of the best milk that Nature and art can produce. The effort must not be confined to experts only. It must have "the help and advice of persons experienced in the right application of things". The effort must be initiated by the most powerful authority in the land—the Government itself. It must be directed to outlining and getting carried out a programme of comprehensive investigation extending from the pasture to the larder, and including dairy herd and farm water supply, cowman and milkman. There is old knowledge, massive and confusing, to be reviewed, and new knowledge to be won. The reapers are many but, though skilled, they are scattered. With these energies joined together the harvest would soon be plentiful.

Let the Government set up forthwith a small commission with large powers to lead the attack on a problem the solution of which would result in the rejuvenation of the race.

Biological Philosophy

Allgemeine Biologie eine Einfuhrung in die Lehre vom Leben Von Dr Max Hartmann Zweite, vollständig neubearbeitete Auflage. Pp xii+792. (Jena Gustav Fischer, 1933.) 38 gold marks.

IN the issue of NATURE of December 17, 1932, we had the pleasure of reviewing a bold and original work on general biology by Prof Woltereck, and now we have before us a still longer and more elaborate work on the same subject by Dr Hartmann, who is a member of the staff of the Kaiser Wilhelm Institute for Experimental Biology at Dahlem. Naturally the subject is treated very differently by the two authors, for whereas Woltereck has attained world wide fame as a zoologist and embryologist, Hartmann's claims for distinction rest chiefly on researches on the Protista (Protozoa and Protophyta) and on the Thallophyta amongst plants. Then again, Woltereck came courageously into the battle, by asserting that in all living things there is a vitalistic factor regulating their actions which is not to be accounted for by the structure or mutual positions of their constituent molecules. Hartmann, on the contrary whilst repudiating materialism as a system of thought unworthy to be regarded as a 'philosophy , nevertheless holds that science can deal only with living things as lumps of matter it must argue 'as if' materialism were true.

Hartmann clearly recognises that human consciousness is the foundation of all our knowledge, that what we call 'matter' consists of presentations to this consciousness, and that most of the qualities with which we invest 'objects' do not inhere in them, but are given to them by the human mind. But there is the further difficulty, that only one consciousness is directly known to us, and that is our own. We infer a similar consciousness in our fellow men from their actions, that is, their movements, and if the view that the human race has grown out of some lower race of animals is correct, then it is impossible to deny something like consciousness, at least to the higher animals. Hartmann's limitation of the ambit of science to the study of material changes, if logically carried out, would condemn us to a philosophy of 'solipsism', which of all forms of philosophy is the most unpractical. We should be forced to attempt to explain the actions of our fellow-men by the chemical and physical structure of their bodies, leaving entirely out of sight their thoughts, feelings and desires, and an anthropology such as this would be worthy only of a madhouse. There can be no arbitrary restriction on the methods adopted by science: its aim is to establish general laws, as Hartmann himself says, to refer the individual to its place in the general scheme of things, and that method is to be preferred which gives consistent results and shows the fundamental similarity of widely differing living things.

We may perhaps illustrate the archaic quality of Hartmann's outlook by giving a brief account of the way in which he deals with the structure of Protozoa. He asserts that protoplasm is primitively a fluid, for he regards its semi-solid or 'gel' modification as secondary: he overlooks the fact that a fluid can have no organisation or definite arrangement of parts: its movements can only be controlled by its boundaries, and the only 'forces' which it can exert are those due to varying surface tension or increase in volume. So Hartmann is driven back on surface tension as the cause of amœboid movement, and still clings to the artificial amœbæ constructed by Bütschli out of oil drops impregnated with hygroscopic salts. Now the work of Jennings, Gray and Pantin has completely shattered this hypothesis and has proved that surface tension plays no part in animal or plant movements, but that the fundamental factor in all movement is the change from the sol to the gel condition or vice versa: that although the blastomeres of a rapidly dividing egg cell *look* as if they owed their shape and arrangement to surface tension, this is an illusion: what really happens in a dividing egg is the 'jellification' of its outer layer at the moment of division, followed by a partial solution between divisions.

It is true that Hartmann does mention in passing Pantin's work, but he asserts that Pantin's conclusion, namely, that in a moving amœba the endoplasm is pressed forwards by the contracting ectoplasmic sheath, does not apply to his (Hartmann's) amœbæ—but this is incredible. The great value of Pantin's work is that it brings pseudopodial movement into line with muscular contraction and shows that the fundamental nature of all animal movement is the same. Hartmann even endeavours to persuade us that the myonemes or contractile filaments of Protozoa and Cœlenterata, smooth muscles and cross-striated muscles, are essentially different things. This is unreasonable in view of the fact, for example, that the myonemes of *Hydra* are replaced by 'smooth muscle' cells in *Obelia* and that smooth muscle has actually been converted into striated muscle by subjecting it to prolonged and increasing tension.

Hartmann gives a large number of extraordinarily interesting facts about the reproduction of the lower organisms: these alone would render the book of very great value. He shows that sex, in the form of conjugation of nuclei, is ubiquitous: his account of sexual and asexual reproduction in *Chlamydomonas* is especially interesting. He arrives at the extraordinary conclusion that even when the conjugating cells appear precisely alike, nevertheless, by means of suitable tests, a male and a female partner can be distinguished, and that therefore the distinction between the sexes is not an 'adaptation' or division of labour gradually evolved in the more complicated organisms, but something fundamental involved in the very nature of life itself. As to the functions of sex itself, he comes to no very definite conclusion: he rejects the view that it is an arrangement made necessary by the gradual 'wearing out' of the vital processes, citing against this theory the experiments in which asexual reproduction has been continued for years *under carefully controlled conditions* without deterioration of the stock. But it seems to us that the significance of sex—as of all other biological phenomena—cannot be understood merely by the exhaustive study of one or two cases, but only by a broad comparative view of the matter, and what such a survey teaches is that sexual reproduction intervenes as a response to the onset of unfavourable outer conditions to which the product of sexual congress, that is, the zygote, is specially resistant. As the experience of all breeders shows that the vigour of the offspring is diminished when it is the offspring of two nearly allied parents, the old view that sex is a device for restoring vigour by enabling the deficiencies of one partner to be compensated for by the excellences of the other seems unlikely to be transcended.

As was to be expected from a member of the staff of the Kaiser Wilhelm Institute, Hartmann accepts wholly the Mendelian interpretation of variation and heredity. He does not see that the modifications which he is forced to make in Mendel's original statement are really the *reductio ad absurdum* of the whole theory. The Mendelian rules were founded on the results of crossing two varieties separated from each other by clear and sharply marked distinctions. Mendel himself expressly stated that he would have nothing to do with differences of 'a more or less character' Since functional differences, which alone are significant in evolution, are always of a 'more or less' character, it is probable that Mendel would have agreed with some of us in regarding the mutations studied by him, however interesting, as having played no part in the formation of species But when Hartmann invites us to believe that probably all mutations are due to the coincident action of a large number of 'genes' distributed at random, then it is obvious that any conceivable result obtained by the crossing of two races or species can be interpreted in accordance with the Mendelian rules, and such assumptions reduce the whole reasoning to a farce In justice, however, to Hartmann, it should be added that even he balks at the theory of Morgan that paired chromosomes break at various places and that pieces of one are incorporated in the other He asserts, and the most recent work bears him out, that the appearances relied on by Morgan, such as the apparent composition of the chromosome out of a linear series of granules, are optical illusions produced by the imperfect resolving powers of the microscope He further insists strongly that there is no such substance as 'chromatin'—that the chromosome is a morphological structure, not a chemical compound

In the concluding pages of his book, Hartmann conducts a polemic against Driesch as the leading vitalist He finds, as others have found before him when they have marched up to it, that Driesch's *position* is impregnable Hartmann admits that Driesch is right in saying that the developing embryo is not a machine, and that no mechanism founded on our present chemical and physical knowledge can be conceived to explain it , but he holds out vague hopes that Driesch's flank may be turned in the distant future by some as yet inconceivable development of 'colloid chemistry' This, in our opinion, is equivalent to a withdrawal from the walls of the fortress defeated But one of Hartmann's objections is worthy of further attention He says that Driesch forgets that the only reason for regarding the embryo as a "harmonic equipotential" system is that every cell has the capacity for developing into the whole In this sentence Hartmann crystallises the most profound discovery yet made by experimental zoology Whilst in some eggs, such as those of Annelida, separate blastomeres have limited powers, this is not due to the quality of the nucleus, which is always totipotent, but, as Driesch has explained, to the specialisation or 'stiffening' of the cytoplasm Now Brachet has shown that a frog's egg may be entered by six spermatozoa One of the spermatozoa unites with the nucleus of the egg constituting the zygote nucleus, the rest become independent nuclei All of them begin to divide and to organise the surrounding cytoplasm into cells What horrific monster will issue from this confusion ? The answer is a normal tadpole If this is not 'control', what is it ? And if it is control, does it matter with what term we label it, 'entelechy' or other ?

E W MACBRIDE

History of Engineering

The Newcomen Society for the Study of the History of Engineering and Technology *Transactions* Vol 11, 1930–1931 Pp xi+203+22 plates Vol 12, 1931–1932 Pp xii+142+13 plates (London Newcomen Society, 1932–1933) 20*s* net each Vol

THE Newcomen Society has but a comparatively small membership its members are so scattered that few are able to attend the meetings in London and New York, but in spite of this its sphere of activity is a large one, and its *Transactions* bear the stamp of authority The common interest of the members lies in the study of invention and craftsmanship, technological processes and engineering construction of all times Thus in the two volumes recently published are papers on the origins of windmills, Roman mining in Great Britain, fire extinguishing engines, railways and locomotives, straw handicraft, Hornblower and the compound engine, electric power supply in England and America mining in Cornwall and the Midlands and other matters, most of the memoirs being excellently illustrated The volumes also contain the annual reports, lists of members, accounts of summer meetings at Sheffield and Lichfield, notes on memorials to engineers, and lastly, Parts 9 and 10 of the valuable analytical bibliography of the history of engineering and applied science It has previously been pointed out that some considerable time elapses between the reading of papers and their appearance in the *Transactions* In the circumstances, this is largely unavoidable, but the publication of these two volumes within a few months of each other is a sign that efforts are being made to overtake the arrears The work of the publications committee is not a light one

The Society has been very fortunate in bringing to light original unpublished records , the value of such material is admirably shown in Mr J G H Warren's paper on "John Nuttall's Sketch Book" While one generally associates the locomotive with a few great names such as those of Trevithick, Blenkinsop, Stephenson, Gooch and others, to its gradual improvement in all its details a host of individuals have contributed One of these individuals was a smith, John Nuttall (1818–90) a craftsman whose work, Mr Warren says, is a lasting challenge to some educational theories of our time when a Master of Arts is held in higher esteem than the master of an art" The profound satisfaction Nuttall found in his daily tasks led him to add to a sketch in his note book Making this kind of work I was in my glore In early locomotives the wheels gave an infinite amount of trouble, and one can realise the pride with which Nuttall drew in his book a sketch of the Forst wrought iron wheel that was made ' Mr Warren reviews the whole history of locomotive wheel construction and in doing so establishes the fame of John Nuttall as a worthy not to be forgotten

The work of another such worthy is recalled by Mr F Bland's paper on John Curr Originator of Iron Tram Roads ' Born in 1756, from 1774 until his death in 1823 Curr was mineral agent to the Duke of Norfolk's collieries in Sheffield, and it was while holding this post that he used cast iron plate rails fixed to the wooden sleepers of a tramway James Outram made the rails, but his name has nothing to do with tram roads , as is often supposed

Among other papers read before the Newcomen Society in 1931 were two on early electricity supply undertakings, Col R E Crompton dealing with The First Installation of House to House Electricity Supply in the United Kingdom ', and Mr G A Orrok with "Pearl Street Station, the First Central Station in the World ' Mr Orrok's paper was based largely on the manuscript left by Dr J W Lieb (1860–1929), who had worked at the Pearl Street Station directly under Edison These papers were read in London on April 15 and in New York on April 16, and created considerable interest, the discussion in New York eliciting some interesting reminiscences from Mr F J Sprague, who as a midshipman in the U S Navy attended the Electrical Exhibition held at the Crystal Palace in 1882 and was secretary to a jury including Fleeming Jenkin, Grylls Adams, Abney, Edward Frankland and Horace Darwin In the discussion in London it was recalled that the *Engineer* in 1882 said that "probably no one has done more to make the electric light a popular success than Mr R E Crompton'

Another side of engineering history is represented by the biographical sketch by Prof J K Finch of "John B Jervis, Civil Engineer" (1795–1885), ' who did more than any other man to make engineering in America a profession", and Mr H W Dickinson's paper on 'Jolliffe and Banks, Contractors", the latter paper being suggested by the centenary of the opening of London Bridge, for which they were the contractors The Dictionary of National Biography" says little about Sir Edward Banks and nothing about his partner, the Rev W J Jolliffe, yet they were both remarkable men carrying out many important public works, and ' indeed they were the foremost firm of contractors in an age of big achievements" Banks began life in the North, building dykes, making canals and cutting tunnels Going to Surrey, he assisted in laying down the Surrey Iron Railway and then, joined by Jolliffe, secured contracts in various parts of the country Their most notable constructions included Waterloo, Southwark, London and Staines Bridges and Sheerness Dockyard They both died in 1835, Jolliffe being buried at Merstham and Banks at Chipstead close by One of the results of the reading of Mr Dickinson's paper was that through the generosity of Mr J J Edwards, chairman of the Bridge House Estates Committee of the City of London, the fine tomb to Banks at Chipstead has been rescued from neglect and thoroughly reconditioned This is only one example of the preservation of a monument through the action of the Newcomen Society

Fossil Vertebrates

Vertebrate Palæontology By Prof A S Romer Pp vii+491 (Chicago University of Chicago Press , London Cambridge University Press, 1933) 26*s* 6*d* net

THIS well printed textbook has been carefully prepared, and will be welcomed by both zoologists and geologists The letterpress begins with a brief recapitulation of some elementary geology to refresh the memory of the zoologist , while each chapter is prefaced by enough anatomy and zoology to enable a geologist to appreciate the meaning of his fossils Though nearly all the illustrations are taken (with acknowledgment) from other authors, most of them have been re-drawn in uniform style, and a few have been improved for the student by making them more diagrammatic. The whole bears the impress of a teacher who is actually engaged in research and has himself made many contributions to our knowledge of the fossil vertebrates about which he writes. The book is well up to date, as shown by the beautiful sketches of the restored skull of the oldest known amphibian, *Ichthyostega*, which was discovered recently in Greenland.

Prof. Romer sometimes enlivens his descriptive matter with speculations and suggestions about various possible courses of evolution. At the outset he favours the theory that the echinoderms and the vertebrates had a common ancestry. Next he speculates as to why so many of the earliest vertebrates were heavily armoured when the jaws of all their kin were feeble. He thinks they may have been thus protected against the contemporary aquatic scorpion-like invertebrates, the eurypterids, which would doubtless have fed on them. In the chapter on birds he points out how at the beginning of the Tertiary period there was real rivalry between mammals and running birds for the possession of the land which was left vacant by the disappearance of the dinosaurs. The course of evolution, indeed, might have been different if birds had succeeded in the conquest.

To emphasise the relationships of some of the great groups, Prof. Romer also makes an innovation. Instead of treating all the earliest members first, he relegates to the end those forms which seem to be the direct ancestors of the next higher grade. The crossopterygian and dipnoan fishes, for example, are placed after the teleosteans so that they may be discussed immediately before the amphibians. At the end of the reptiles the dinosaurs are next to the birds, which are said to be "so close to the archosaurians that we are tempted to include them in that group". The Theromorpha, or mammal-like reptiles, are removed from the other reptiles and placed between the birds and mammals.

The volume concludes with a bibliography and a synoptic classification of vertebrates, in which the geological and geographical range of the extinct genera is indicated. The localities of the various fossils, however, are always only vaguely given, and we think that Prof. Romer would have made his valuable work still more useful, at least to advanced students, if he had recorded the sources of the chief specimens more precisely.

A. S. W.

University Omnibus

The Yearbook of the Universities of the Empire, 1934. Edited by Sir H. Frank Heath. (Published for the Universities Bureau of the British Empire.) Pp. 24+xxxii+1010+vi. (London: G. Bell and Sons, Ltd., 1934.) 15*s*.

THOUGH the crisis of distribution may not be so intense in the world of knowledge as in its commercial counterpart, it is yet sufficiently well marked to make us grateful for anything that serves to lessen the labour involved in its acquisition. There are, so we are informed by the preface of the 1934 Universities Yearbook, seventy universities within the confines of the British Empire—and each takes a growing interest in the affairs of the other. This interest has been forced upon them by such facts as that in 1933–34 (excluding Trinity College, Oxford, from which no return was received), there were 5,180 students from other countries in the universities and university colleges of Great Britain and Ireland.

Like a pudding in the eating, the measure of the value of a reference book lies in its use. It is hard otherwise to appraise it, but this being the last number to be produced under the editorship of Sir Frank Heath, who retires from his post of honorary director of the Universities Bureau of the British Empire this summer, it may not be amiss to note some of the changes that have taken place in the make-up of the 'Yearbook' during his five years of office.

If a reference book is to be judged by its index, the 'Yearbook' has a good claim to praise. To prepare an adequate index of names, it is true, is but a matter of care; but the compilation of a general index is another matter. Here, if anywhere, the skill and knowledge of the editor is displayed. Compared with what it was in 1929, the general index of 1934 is a vast improvement.

Other alterations have been introduced by Sir Frank into the appendixes, of which there are now thirty. For example, the section dealing with professional bodies has been considerably enlarged. This year there has been collected in one place (Appendix XXII) on a uniform system information dealing with admission to the several universities of Great Britain and Ireland. It is a damning indictment of unregulated effort. It is a wonder that any student has the temerity to attempt entrance, so diverse are the exempting examinations, special exemptions, special regulations and the like.

Very valuable collections of information are to be found in Appendixes XXIII and XXIV The former gives particulars of the less 'limited' aids to advanced work such as postgraduate scholarships, fellowships and research grants (mostly tenable by British subjects) in Great Britain, the Dominions and foreign countries The latter gives a short account of the purpose of the more important centres of scientific research and information within the Empire

If one criticism and one suggestion be permitted, it is that though science is adequately covered, there is no reference whatever to archæology, history, economics, or, in short, the social and humane sciences There should be

With advantage, too, the section devoted to Industrial Scientific Research (pp 849–859) might be developed into something as big as the American National Research Council's publication on industrial research laboratories Admittedly it would add fifty more pages to the 'Yearbook", but it would be worth while Teachers want to know where they are likely to be able to place promising students , or what firms are prepared to admit advanced students and research workers and under what conditions , and lastly, such an amplification would have the intangible but very real effect of bringing industry and scholarship closer together

The "Yearbook" is essentially a reference work purchased by institutions, and it is not intended for armchair reading Price and bulk, therefore, need not cause too great anxiety to the editorial staff Indeed the fuller the information, the greater the value and the greater the possible sales In any event, even now, every university, every college and every British embassy and consulate ought to have a copy as a matter of course Its uses are infinite, and abroad it would help to bring foreign students to England and into closer touch with our learning and culture, and thus make for better international understanding

The publication of the "Yearbook" is one of the primary objects and justifications for the existence of the Universities Bureau of the British Empire Sir Frank Heath will be able to retire, not to inactivity we hope, secure in the knowledge that the "Yearbook" has grown in scope and usefulness under his care, and that his successor will have the incentive of successful achievement of high aims

Short Reviews

(1) *Secret Ways of the Mind a Survey of the Psychological Principles of Freud, Adler and Jung* By Dr W M Kranefeldt Translated from the German with a Preface by Prof Ralph M Eaton Pp xl+188 (London Kegan Paul and Co , Ltd , 1934) 6s net

(2) *A Survey of the Science of Psychology* By Prof J R Kantor Pp xvii+564 (Bloomington, Ind The Principia Press, Inc , London Williams and Norgate, Ltd , 1933) 16s net

We consider these two books together, because, although they are scarcely comparable in any other sense, they both take up a definite attitude as to scientific method Prof Eaton, the translator of the first book, points out that the official psychology, craving for the methods of the exact sciences, and concentrating on what can be measured, has forgotten its original subject, which is human nature This is one reason why the unofficial psychology of Freud and Jung and Adler has swept over Europe and America Dr Kranefeldt's monograph, with an introduction by Jung himself, may be recommended as an excellent critical survey of this movement

Prof Kantor also aims at a truly scientific method, but he is too wise to be content with quantitative measurement, with the statistics of learning curves and intelligence tests, when human nature at large, with its joys and its sorrows, its loves and its ambitions, is the real subject of investigation Also, though he admits that the behaviouristic is more scientific than the mentalistic psychology, he is no behaviourist His organismic' or interactionist point of view, he claims, enables him to steer clear of the mistakes of both these other schools We believe he justifies his claim, and we are quite sure that his conception of psychology has enabled him to present a very broad and suggestive treatment

The Organism of the Mind an Introduction to Analytical Psychotherapy By Dr G R Heyer Translated by Eden and Cedar Paul Pp xiii+271+37 plates (London Kegan Paul and Co , Ltd , 1933) 15s net

Mind and body are not two distinct spheres of being Their mutual influence is shown, among other phenomena, by neuroses which occur when the psychogenic disturbances from which a patient suffers manifest themselves chiefly as impairments of bodily functions In elaborating the experimental foundations of this view, the author attempts to show the existence of a series of psychophysical 'cycles' or 'spheres' in which life variously and progressively discloses itself as it moves from the primitive to increasingly differentiated phases and forms A description of the chief psychotherapeutic methods completes the technical exposition of the volume

Besides the qualified opinions of the author about the various points raised, the book will be found most interesting and useful as an introduction to the new psychological theories such as autosuggestion, analysis of the unconscious, psychoanalysis, individual psychology and analytical psychology, which have done so much in bringing psychology and medicine together The unitary view of life adopted by the author, which he rightly traces back to the pre-Socratic thinkers, gives an added interest to his general exposition

Leçons sur les fonctions univalentes ou multivalentes professées à la Sorbonne Par Prof Paul Montel Recueillies et rédigées par F Marty, avec un Note de Henri Cartan (Collection de monographies sur la théorie des fonctions) Pp iv+159 (Paris Gauthier-Villars et Cie, 1933) 40 francs

THERE are two methods of studying analytic functions The first consists in examining the points where the function becomes peculiar—its singularities These points characterise functions of the same group and at the same time give them individuality The second consists in examining properties at ordinary points—the region of regularity This interesting book adopts the second method The author seeks to classify functions according to their order of multivalence, that is to say, the number of times which the function takes the same value The univalent functions are particularly important since they are fundamental in the theory of conformal representation A univalent function when substituted for the variable leaves the order of multivalence invariant

The book is founded on a course of lectures given at the Sorbonne by Prof Montel and has been ably edited by M Marty, who has made many original contributions In an appendix, M Cartan considers the possibility of extending the idea of univalence to functions of several variables

Functions of a Complex Variable By Prof Thomas M MacRobert Second edition Pp xv+347 (London Macmillan and Co, Ltd, 1933) 14*s* net

THIS second edition of this useful book will be warmly welcomed The theory of functions of a complex variable plays an increasingly important part in the applications of mathematics to physical problems The student who desires to make these applications without delving too deeply into abstract theory will find here just the material which he requires, clearly set out and with sufficient rigour for his needs Bearing in mind the difficulties of the beginner, Prof MacRobert has tempered the arithmetical approach to the subject with a wise admixture of geometrical intuition, and has thereby succeeded in producing a book which may be easily consulted on any particular point such as contour integration, special functions, or the linear differential equation of the second order The new edition differs mainly from its predecessor in the addition of appendixes on the hypergeometric function, Legendre functions and Fourier integrals

The New Psychology and Religious Experience By the Rev T H Hughes (Halley Stewart Publications, 2) Pp 332 (London George Allen and Unwin, Ltd, 1933) 10*s* 6*d* net

IT can be safely said that religion has now weathered the storm of scientific criticism If it has beaten back the forces of materialistic philosophy, it is because of its reliance on the reality of religious experience In this very able book Principal Hughes defends that experience against the disintegrating criticism of the new psychology, especially of behaviourism and psychoanalysis He discusses the origin and meaning of religion in the light of these systems, and shows that God and conscience are not mere projections of the self, but independent realities which give a real value to religious experience in general and to Christianity in particular The expert way in which the various problems raised are treated is a tribute to the ability of the author and to the great importance of his subject T G

(1) *La géométrie à la portée de tous* Par J Poirée Pp 117 (Auch Imprimerie Cocharaux, 1931) 20 francs
(2) *L'Arithmétique à la portée de tous nombres entiers, fractions, calculs approchés* Par J Poirée Pp v+97 (Paris Gauthier Villars et Cie, 1932) 25 francs
(3) *L'Algèbre et la trigonométrie à la portée de tous* Par J Poirée Tome 1 *Calcul algébrique et équations* Pp v+57 15 francs Tome 2 *Etude de la variation des fonctions* Pp vi+44 15 francs (Paris Gauthier Villars et Cie, 1933)

THESE four little books represent the limit of simplification and are intended for those who have never studied mathematics at all For these they are probably too difficult To the teacher of the elements they might offer some useful ideas of simplified exposition

Vorlesungen uber Boden Mikrobiologie Von Prof Dr August Rippel Pp viii+161 (Berlin Julius Springer, 1933) 6 90 gold marks

THIS handy and accurate book is packed with facts concerning a wide range of the bacteriology of soil and water It would make an excellent foundation for a course, though its value to the student is reduced by the absence of any references except to textbooks The names of many authors are given, but most of them are Central European The language and planning of the book are clear, and the work can be cordially recommended

Physics and the Public Mind

By PROF. HERBERT DINGLE, Imperial College of Science, South Kensington

AN epoch in science is invariably followed by a general change of attitude towards life as a whole, which is none the less profound because it lacks the dramatic suddenness of its precursor. Newtonian mechanics had no direct bearing on vulgar hopes and fears, yet the popular reaction to the appearance of a comet in the eighteenth century was not that of the sixteenth, even among those who knew nothing of gravitation. Organic evolution was not obviously concerned with sociology, yet to Spencer the word 'progress' meant something other than it meant to Rousseau. No scientific idea lives to itself or dies to itself.

The responsibility which this fact lays on the shoulders of the man of science weighs not on his researches but on his treatment of their results. By the very essence of his calling he is consecrated to truth, and he must know all her ways, whatever their effect on human institutions and beliefs. But, by the same token, he must see that his report on what he finds does not mislead; above all, that it does not contain a denial of the spirit of research itself.

> For I say, this is death and the sole death,
> When a man's loss comes to him from his gain,
> Darkness from light, from knowledge ignorance.

Difficult as it must always be properly to estimate current events, it is clear beyond question that the post-War years have seen a development of fundamental physical ideas such as history has rarely recorded. Already the theoretical physicist of middle age, if he has time to muse at all, contemplates the outlook of his youth with something of the feelings with which he regards medieval thought. It is only fitfully that he realises, with a mild shock of surprise, that this archaic attitude was once natural to himself and is still part of the mental equipment of most of "that section of his contemporaries which is called the public". On the world at large the impact of the new ideas must necessarily work more gently and slowly, but no less inevitably. Sooner or later, social institutions, literature, art, religion will reflect the change, and it is not too early to inquire how the public mind is reacting to the scientific revolution itself, for on that reaction will depend the more subtle developments in the various fields of practical human interest.

At first sight the omens are pleasing. Thanks largely to broadcasting and the great skill in exposition shown by certain of our physicists, popular attention is given to things scientific probably in greater measure than ever before. Not only so, but the recognition is general that science has something vital to contribute to the various departments of thought, feeling and action, and there is a genuine desire to know what that contribution might be. Superficially this is all very satisfactory.

When we look deeper into the phenomenon, however, grounds for misgiving appear. The remarkable fact that books of science have become best sellers admits of two possible explanations: either the most widespread desire of the public has changed, so that it is now for scientific thought instead of thoughtless diversion, or else books of science have changed so as to provide thoughtless diversion instead of scientific thought. Unfortunately the latter alternative appears to be nearer the truth.

There was a time when the writer of science for the public demanded considerable mental effort from his readers, as a tribute befitting the dignity of his subject. He showed them the steep and thorny way to heaven. Nevertheless he led them there if they were willing to follow him. To-day we are only too familiar with the primrose path to the everlasting bonfire. Writers such as Ball and Lockyer not only described the achievements of science; they indicated also the steps towards those achievements, appealing to reason to approve the course as well as to admiration to applaud the goal. The modern successors of these men are too prone to present the achievements, made alluring by their plumage of paradox, and to prevent access to the steps by a mysterious guardian who, finger on lip, whispers in hushed tones the magic word, Mathematics. The consequence is inevitable. The reader not only enjoys the fun, but also feels at liberty to claim science in support of whatever philosophical or religious dogmas he may hold, paradox lending itself readily to favourable interpretation by contradictory creeds. Any scruples of conscience he may feel at taking this royal road to learning are allayed by the assurance that he need not think for himself since in any case the argument is beyond him. Small wonder that the age when science is most difficult is the age when it is most popular.

To make the point definite, let us concentrate attention on one of the most prominent elements of the new nescience—the doctrine of indeterminacy. It is widely preached that modern science is essentially indeterministic, and that therefore we may not only believe in human free will if we like—which, of course, we could always do—but also claim scientific support for it. This idea, emanating from men of science with the highest credentials, has spread, both directly and through various grades of intermediary expositors, to the pulpit, the newspaper and the market-place. Authority for the idea is everywhere; evidence for it, however, is far to seek. As an example we may cite an earnest little book recently written by a doctor of science with the object of showing the plain man the trend of modern science and philosophy. "The work of Dirac," he writes, "suggests a somewhat transcendental nature of matter, while that of Heisenberg is particularly significant because it has knocked the bottom out of the idea of predestination, put probability in its place, and shown that there is even a physical basis for the belief in free will as a factor of existence." When we seek for evidence for this remarkable statement, all we meet with is the following: "The mathematicians are among the most trustworthy of intellectual guides. Physics is essentially a mathematical subject, and over some of the ground we have to traverse the experimental physicist will still accompany us, but eventually we may have to trust the mathematician alone." When a doctor of science (who, it may be said, implies that he himself is unable to follow the mathematical arguments) can write in these terms, we may wonder whether the twentieth century differs intellectually from the sixteenth except in the substitution of the mathematician for the medieval philosopher.

The protest will at once be raised: 'What can one do? Theoretical physics is indisputably beyond expression in popular terms, and is one to keep some of the greatest intellectual adventures of history as a secret possession because they cannot be described in their fullness without mathematical language?' The reply is that the evil does not lie in the incompleteness of the presentation—that must always exist—but in its character. Conclusions are presented as mathematically demonstrated which mathematics has not only not demonstrated but is also inherently incapable of demonstrating. Mathematics is thus portrayed as the magic wand of the few instead of the concentrated reason of all. Once the supreme expression and inspired Word of Reason, it has become an indulgence, granting absolution for the wildest excesses of irrationality. Instead of being a mental tonic, its very name has become a mental opiate, and elementary fallacies which a generation ago would have been detected by the most ordinary of thinkers, now deceive the acutest minds, which lie bemused under its spell.

To exemplify this it is not necessary to take the more outrageous application to human free will, which in actual fact has not yet been shown to bear any relation at all to physics. We can go deeper and look at the purely inorganic indeterminacy. The basic expression of this doctrine is to be found in Prof. Dirac's "Quantum Mechanics": "When an observation is made on any atomic system that has been prepared in a given way and is thus in a given state, the result will not in general be determinate, i.e., if the experiment is repeated several times under identical conditions several different results may be obtained." Let us see how this astonishing conclusion has been reached.

The whole of quantum mechanics, of which this is a part, has been built up as an attempt to explain the results of experiment. Now not only is it true that not one experiment has ever been repeated several times under identical conditions without the same result having been obtained (allowing, of course, as has always been done, for the small errors inevitable in human experiment), but the very statement which Dirac makes is based on this constancy. It will not do, for example, if he can say merely that a spectrum produced in Prof. Fowler's laboratory on such and such a date contained a line of which the wavelength on the following day appeared to Prof. Curtis to be so many units in terms of a scale which some years before had been found by an employee of Messrs. Hilger to bear a certain relation to a *still earlier state of the standard metre*. Unless he can say quite generally and definitely that the wave length of $H\alpha$ is that and nothing else, the whole system of quantum mechanics collapses for want of evidence. If, then, the conclusion quoted is true it automatically knocks away its own support and all reason for believing it vanishes.

This argument is very simple, and it is irrefutable. It makes no appeal to the algebra of matrices or group theory, but rests on the elementary logical principle that an argument whose conclusion violates its premises cannot be sound. Twenty years ago it would have occurred at once to any person of ordinary intelligence, but to-day what do we find? Half the world proclaim with joy that at last the most exact of sciences has established the freedom of the will, while the rest sit in bewildered silence, restraining the protest they long to make from fear that mathematics might have ways of disproving the obvious. The spectacle would be amusing if it were not so serious.

Let us understand the position clearly. It will not do to scoff at quantum mechanics and look upon the modern developments of physics as a malignant growth from which science may recover under the surgeon's knife; they are, on the contrary, a mutation in the authentic line of development of thought. Dirac is not the fool he may superficially appear; he possesses one of the very greatest minds our age has produced. The fault is not that we are living in an age of darkness, but that the brilliance of the time is making us blind, that loss comes to us from our gain and ignorance from our knowledge. What is wanted is a reformulation of the philosophical foundations of science, so that sense shall not have to express itself in nonsensical terms. The philosopher may give it to us but there is more hope from the man of science, for in the present situation it is not so difficult for him to acquire sufficient philosophical knowledge and acumen as it is for the philosopher to familiarise himself with physics. But the manner of its coming is of minor importance; the great thing is to get it.

We are not unfamiliar with this demand or with attempts to satisfy it, but there is little sign that the real desideratum is properly understood. It is not sufficient to impeach Victorian assumptions and declare how much wiser we are now. The new philosophy must not merely reveal the falsity of the old; it must embody all its truth. To resort once more to imagery, the relation of what we are offered to what we need is somewhat as follows In surveying the physical landscape we have discovered certain facts which we cannot fit into the same plan as the more familiar ones every attempt to co-ordinate them involves us in absurdity There are two ways out of the difficulty The first, which appears to be the only one attempted—or, at any rate, popularised—so far is to assume that the landscape *is* absurd, and that instead of marvelling that we cannot make a rational conception of it, we should rather pity our former inability to see that absurdity is the essence of Nature The second way, which at least seems worth trying, is to change our point of view until the spectacle again becomes coherent To do this is not easy it is much pleasanter to lie in a bed of chaos and smile at our folly in thinking reason worth while But the time may come when we shall regret such a choice

It is a question for the specialist now, but in a few decades it will be a matter of universal importance, for the abstract thought of one generation, operating unperceived by the majority, directs the practical activities of the next It is not merely scientifically indefensible, it is socially tragic when a tremendous forward leap in human thought, about which the public is curious to a degree never before witnessed, is represented as a negation, by an unintelligible formula, of all that has been proved trustworthy in the past, when a man like Sir Arthur Eddington, who is responsible for the most valiant attempt yet made to form a positive unity of the new ideas, can for public instruction give as a summary of the whole situation the vague and inaccurate phrase, "Something unknown is doing we don't know what", when Sir James Jeans can so far forget his own admirable work as to write, "Heisenberg now makes it appear that Nature abhors accuracy and precision above all things", and when the only means the truth seeker has of detecting the falsity of these statements—namely, the exercise of the reason with which he is naturally endowed—is made impotent by the suggestion that mathematics, which he has no time to learn, has discovered how to prove the illogical There is here a situation far more serious in the long run than many of the problems which agitate public life to-day

Freedom of thought may be attacked in two ways Many recently have been moved to protest against the use of external force for this purpose But, regrettable as such control is, it cannot by its very nature constitute a real limitation Stone walls do not a prison make, and history has shown that the blood of the martyrs is the seed of the Church Infinitely more dangerous is the menace to thought from thought itself When, in the name of science, criticism is not chained but drugged, and unreason, in robes *not its own*, receives the homage meant for reason, thought is enslaved indeed Those who are wise enough to see how the social life of a people is related to its mental state will scarcely contemplate the future with equanimity

Diet and Dental Disease in Man

IT is now well established that there is an intimate relationship between the structure of the teeth in animals and the composition of their food supply, as well as between the latter and certain forms of dental disease The work of Mrs Mellanby on these problems has already been referred to in these columns (NATURE, 125, 604, 1930 127, 977, 1931) The results of these researches led naturally to an investigation of the problem of dental caries in human beings, along original lines, with the view of determining whether a similar relationship between diet and structure and disease held here also An interim report of a clinical trial by the Committee upon Dental Disease was issued in 1931 (NATURE, 129, 83, 1932) and is now followed by the full account of Mrs Mellanby's experiments upon the effect of diet on dental structure and disease in man*

An account is given first of normal and abnormal development and structure of the teeth by normal is meant the perfect structure which can be obtained in animals receiving vitamin D and a sufficiency of calcium and phosphorus The normal tooth is creamy white, smooth and shiny in appearance, the enamel is relatively thick and regular in outline, with a more or less regular, systematic arrangement of the prisms and comparatively little pigmentation The dentine is relatively thick and shows no poorly calcified areas (or interglobular spaces) Such spaces are rare in animals living under natural conditions, but in civilised man, who lives under artificial conditions, their presence is the rule rather than the exception Teeth can be graded according to the surface character of the enamel, even while still in the mouth good correlation was found between surface texture and minute structure in the shed or extracted teeth submitted to microscopical examination, so that it is possible to infer the histological structure of teeth while still in the mouth

In a collection of more than 2,000 shed and extracted teeth, it was found that, whether assessed by surface or histological examination, the majority of the deciduous teeth were defective (hypoplastic) in structure, the incisors being the best and the second molars the worst formed Teeth collected from private sources were better calcified than those from public elementary school children The majority of the permanent teeth were also hypoplastic The teeth of two groups of children were also examined, the first in a hospital for surgical tuberculosis (1,684 deciduous and 1,453 permanent teeth) and the other in cottage homes (12,807 deciduous and 14,078 permanent teeth) 21 per cent of the deciduous teeth of the latter group and 7 per cent of those of the former had no defects , 32 per cent of the former's but only 5 per cent of the latter's were very hypoplastic As regards the permanent teeth, 1 per cent were normal in the hospital children and 24 per cent in the cottage homes children, 43 and 8 per cent being very hypoplastic respectively Histological examination indicated that in the majority of deciduous teeth the part formed before birth was well calcified, the defects beginning to form how ever, soon after birth

---

* Medical Research Council. Special Report Series, No 191 Diet and the Teeth, an Experimental Study Part 3 The Effect of Diet on Dental Structure and Disease in Man By May Mellanby Pp 180. (London H.M Stationery Office, 1934.) *5s* net.

As regards caries, of which three degrees were arbitrarily recognised, it was found that 27 per cent of the deciduous teeth of British children were free from the disease, while 42 per cent were very carious 67 per cent of the incisors but only 4 per cent of the second molars were caries free , 10 per cent of the incisors and 63 per cent of the second molars were severely affected The teeth collected from private sources were less carious than those of the children from public elementary schools Caries was also more prevalent in the children in hospital than in those in the cottage homes 47 per cent of the teeth in the former group and 73 5 per cent of those in the latter were free from the disease Caries was extensive in 22 per cent and in 7 per cent respectively in the two groups 68 per cent and 83 per cent of the permanent teeth were healthy The incisors and canines were the least and the first molars the most affected

The data given above suggest that there is a close relationship between the structure of the teeth and their liability to caries It was found on analysing the figures more closely that, of the deciduous teeth diagnosed as normal by surface appearance or by the histological structure of the enamel or dentine, 77–83 per cent were free from caries, whilst 2–10 5 per cent were severely affected On the other hand, of those diagnosed as very hypoplastic, only 7–9 per cent were free from caries, 60 5–73 per cent being severely affected The same general association holds also in the case of the teeth examined in the mouth, including the permanent teeth Mrs Mellanby concludes "It can therefore be stated as a general hypothesis that there is a close direct association between structure and caries "

Only in 11 2 per cent of the deciduous teeth was no direct association found, 5 1 per cent being too carious for the structure and 6 1 per cent less carious than might have been expected from the structure Examination of the sections for the presence of secondary dentine and its structure when present showed that teeth of poor structure yet free from caries had well calcified dentine, whilst the latter was usually imperfectly formed when caries appeared in a tooth originally well formed In other words, the defensive reactions of the teeth after eruption play a part in the association between structure and caries Only about 2 per cent of the 1,500 teeth examined were gross exceptions to the two hypotheses of direct association between structure and incidence of caries and that there may be a change in the resistance of the teeth after eruption which is indicated by the character of the secondary dentine

The next step was the experimental confirmation of the relationship between diet and structure and so between diet and caries in human beings Four successive investigations were made in a Sheffield Hospital for surgical tuberculosis and afterwards two concurrent tests on children in the Birmingham Cottage Homes, one lasting for two years and the other for a year and a half The ordinary diets given the children were those commonly considered adequate in all respects the modifications made were additions of oatmeal, olive oil, cod liver oil or radiostol (irradiated ergosterol), and milk, butter and eggs, or removal of oatmeal and other cereals The energy value, fat, protein and carbohydrate content, as well as the amounts of calcium and phosphorus present, were kept as constant as possible in the different diets , on the cereal-free diet the carbohydrate was reduced and the fat proportionately increased In the Sheffield investigations, considering only the children less than six years old (as the average age in the earlier investigations was about eight years), it was found that the average number of teeth per child showing initiation or spread of caries was reduced from 5 0 on the diet containing no extra vitamins A and D, but with increased oatmeal, to 0 37 on the cereal free diet with addition of cod liver oil and radiostol solution daily The average number of teeth per child in which caries showed hardening was increased from 0 2 to 4 7 The Birmingham results bore out those previously obtained in Sheffield and showed that vitamin D is an important factor in checking the initiation of fresh caries, diminishing the spread of old caries and arresting the infective process in many carious teeth

Following the discussion of the experimental evidence in favour of the thesis that diet and dental disease are intimately related through the variations in structure of the teeth which can be produced by changing the diet, the report considers the racial distribution of caries, since the thesis ought to be capable of explaining the relative immunity or susceptibility of races and communities in various parts of the world A review of the available evidence suggests that the main conditions responsible for immunity from dental decay are prolonged breast feeding with a supplementary diet often for three or even six years and a high intake of vitamin D (or exposure of the body to the sun) together with a sufficiency of calcium and phosphorus A high carbohydrate diet (cereals or potatoes) is compatible with good teeth provided the supply of vitamin D, calcium and phosphorus is also sufficiently great Caries is especially rampant where cereals form a large part of the diet, breast-feeding is short, the intake of milk, eggs and animal fats is small and sunshine is negligible or rendered ineffective by clothing.

It has thus been shown that perfectly calcified and regularly arranged teeth can be produced by including in the maternal diet during pregnancy and lactation, and in the diet of the offspring at the time of dental development, substances containing much vitamin D, calcium and phosphorus, such as milk, eggs, fish and animal fats, and that cereals, especially those rich in embryo such as oatmeal, tend to produce hypoplastic teeth and call for a correspondingly larger supply of calcifying foods for good development. It has further been established that the teeth of the majority of children in Great Britain are imperfect in structure; that dental caries is more likely to attack such teeth than perfect teeth with normal enamel and dentine and a smooth surface; that the resistance to caries can be increased independently of the original structure by giving a diet containing much vitamin D, calcium and phosphorus or decreased by a diet rich in cereals. If these general principles of feeding were widely adopted, there is little doubt that dental caries (and also pyorrhœa, to which a deficient intake of vitamin A predisposes) will cease to be the scourge they are at the present time. It may finally be pointed out that none of these conclusions conflicts with the generally accepted idea that the *exciting* cause of caries is the growth of micro-organisms in the mouth; the novelty is the proof that the tooth can resist the onslaught of the microbes by the absorption and assimilation into the body tissues of certain specific dietary factors.

Obituary

Mr. E. M. Eden

EDGAR MARK EDEN died on February 10 at the age of sixty years. He was the eldest son of William Eden, an artist, and was educated at University College, London. After a period with Messrs. Willans and Robinson, ended by ill health from which he was never wholly free, he became a demonstrator at University College under Prof. Hudson Beare, by whom he was greatly influenced. In 1907 he became lecturer at Armstrong College, where he remained until his life work began in 1915.

The National Physical Laboratory had undertaken the testing of all gauges for the manufacture of munitions. The old methods were inadequate to deal with the immense number of gauges, and especially screw gauges; entirely new and simpler methods were necessary. Here Eden's genius found its appropriate field. Many others shared in the work, but they would agree that every method finally adopted owed something to his inspiration, and that many of the most important owed everything. The simple machines that he devised for the most intricate measurements did much more than solve an urgent war problem. They enabled British manufacturers to test their own products and to raise appreciably their standard of accuracy. In the list of those who have led the post-War reconstruction of our industries Eden's name should stand high.

In 1919 Eden joined the original staff of the newly founded Research Laboratories of the General Electric Co., Ltd., as head of the workshops. His work now covered a much wider range, but knowledge of it was necessarily confined to a narrower circle. Discerning visitors to the Physical Society's Exhibition will have realised that its quality remained unchanged; but only his colleagues know how much of any success they may have achieved is due to it.

It is impossible to describe examples of his work in a few words; reference must be made to published accounts, for example, in Rolt's 'Gauges and Fine Measurements' and in the *Journal of Scientific Instruments* (May 1922, and vol. 2, p. 119). All his work had a common feature: an economy of means and of material characteristic alike of the best science and the best art. Among modern Englishmen only Rayleigh and Horace Darwin can be compared with him in this matter. Like them he always went straight to fundamentals; he would not even take a hackneyed formula from a textbook; he always worked it out for himself. The colleague who brought him a sketch was often disconcerted to find the final apparatus shorn of all his cherished ingenuities; but it always worked at a first trial, and achieved exactly what was required of it, neither more nor less.

The same hatred of elaboration and ostentation inspired Eden's private life. He loved wild flowers but not the formal garden; the elegance of Mozart but not the grandeur of heavy orchestration. It made him a true peace lover; only his duty to his young family persuaded him, after a bitter struggle, to take even an indirect part in hated strife. Yet he was no shrill pacifist; quarrels vanished like smoke before his genial smile and kindly, but caustic, humour. He was a perfect host; and his accounts of workshop doings at staff meetings were so entertaining that they became recognised as among the Laboratory treats. We are all much poorer for his loss, though the world at large may never know it. He leaves a widow and four sons.

Dr. H. M. Cadell

THE sudden death of Dr. H. M. Cadell on April 10 at the age of seventy-three years has deprived Edinburgh and its neighbourhood of a distinguished scientific worker and of one who played a conspicuous and most useful part in the life of the community. Born in 1860, he was educated at the University of Edinburgh and at

Clausthal Royal Mining Academy, Germany He was one of the first band of students who studied under Archibald Geikie, and at the age of twenty-three years he became a member of H M Geological Survey He always regarded it as a privilege that he was sent to the field as a junior member of the staff under Peach and Horne in the survey of the north-west Highlands, and an account of his laboratory experiments illustrating the mode of production of the complicated tectonics of that region is included in their classic memoir On succeeding to the family estate in 1888 he retired from the Survey after only five years' service, but his interest in geology and geography continued unabated, and he was the author of a long series of geological and geographical papers, many of which were the results of observations made during his frequent and extensive travels

Cadell's more important publications dealt with the oil shale field and general geology of West Lothian, and with the geological history of the Forth valley He was essentially a practical geologist and took an active part in the development of the coal- and oil shale fields of West Lothian, and in the reclamation of the muddy foreshore along parts of the Firth of Forth He was also interested in the exploitation of the coal resources of Spitsbergen

The various scientific societies in Edinburgh particularly the Royal Scottish Geographical Society, the Royal Society of Edinburgh, and the Edinburgh Geological Society owe Dr Cadell a great debt of gratitude for many services rendered and for generous financial support He led the life of a country gentleman and became a county magnate, serving in various capacities on the County Council of Linlithgow, and becoming Deputy Lieutenant He also served in the 'volunteers' for twenty-four years and retired in 1906 with the rank of Lieut Colonel and Hon Colonel, V D

Cadell's services to the University of Edinburgh were many, and special mention may be made of the interest he took in the founding of the chairs of mining and of geography As a recognition of his scientific attainments and public work he was awarded the honorary degree of LL D by the University in 1932

It is rare to find combined in one personality gifts of such a varied nature, and he will be greatly missed in Edinburgh T J JEHU

DR J P VAN DER STOK

JOHANNES PAULUS VAN DER STOK was born on January 14, 1851, at Zuilen, near Utrecht He studied at the University at Utrecht and took his degree of doctor in physics and mathematics in 1874 In 1877 he went to Java as sub-director of the Magnetic and Meteorological Observatory at Batavia, was appointed director in 1882 and retired as such in 1899

Van der Stok's first publications dealt with periods in terrestrial magnetism and meteorology in relation to the sun and moon, and the observatory at Batavia co operated in many international researches in seismology, terrestrial magnetism and cloud studies His most important work, however, were his tidal studies, based on Darwin's method By a skilful arrangement of direct readings of tide gauges at well chosen hours, and many original methods of discussing the results, he was able to disentangle completely the very complex tidal phenomena in the Archipelago The results have been published in a series of sixteen papers and in the atlas 'Wind, Weather, Tides and Tidal Streams in the East Indian Archipelago" Tide prediction, highly important for shipping especially near Sourabaya, has since been carried out by Van der Stok's methods largely by native assistants

After his return to Holland, Van der Stok became director of the oceanographical department of the Meteorological Institute at De Bilt and remained so until 1923 There his principal work was the supervision of the publication of oceanographical atlases of the Indian and Atlantic Oceans, but he continued also his tidal work and published an "Elementary Theory of the Tides" with numerous tidal constants for the East Indian Archipelago, which has been translated into German He also published through the Amsterdam Academy of Sciences many studies in climatology and dynamical meteorology He was the first to introduce stability' as a numerical indication of the degree of variability in direction of wind and current vectors, and one of the first to use and investigate frequency tables and curves in climatology—we need only mention his treatment of tides in the North Sea and of the climate of the North Sea deduced from lightship observations After several years of illness, borne with exceptional patience and cheerfulness, he died on March 29, 1934, at the age of eighty three years Throughout the world his name will be gratefully remembered

E VAN EVERDINGEN

THE death is announced of Frederick William Christian, anthropologist and explorer, city librarian of Christchurch, New Zealand, which took place at the age of sixty six years at Wellington, N Z F W Christian the son of E H Christian, was born at Putney Hill on June 15, 1867, and educated at Eton and Balliol College, Oxford After taking his degree he became interested in the exploration of the Pacific, and more particularly of the islands of Micronesia His ethnographical observations in this area were of enduring value and continue to be the best and most authoritative account of some of the lesser known islands His best-known and most frequently quoted work is "The Caroline Islands" (1899) He also published 'Eastern Pacific Lands" (1910) and a comparative study of a number of the Oceanic languages He was a frequent contributor to the publications of the Polynesian Society and other scientific journals

News and Views

Sir Sidney Harmer, K B E, F R S

SIR SIDNEY HARMER, who received the Linnean Medal at the anniversary meeting of the Linnean Society on May 24, has had a long and distinguished career as a zoologist, and is still actively engaged in research His published works deal for the most part with two widely different groups of animals, the Polyzoa and the Cetacea His first paper (1884) described the anatomy of *Loxosoma*, and his most recent, issued this year, was the third instalment of his great report on the Polyzoa of the *Siboga* expedition Perhaps his most outstanding contributions to science have been the demonstration of the chordate affinities of *Cephalodiscus* (published in an appendix to McIntosh s *Challenger* Report, 1887), and his discovery of embryonic fission in cyclostomatous Polyzoa (1893) While superintendent of the University Museum of Zoology, Cambridge, Harmer, in collaboration with the late Sir Arthur Shipley, planned and edited the great Cambridge Natural History the ten volumes of which appeared between 1896 and 1909

IN 1909 Harmer left Cambridge to become keeper of zoology in the British Museum (Natural History) and ten years later he was appointed director of that institution Shortly after he went to the Museum he devised a scheme with the co-operation of the Board of Trade and the Coast Guard, for recording the occurrence of Cetacea stranded on the British coasts, and in the course of twenty years a vast amount of information has accumulated in regard to the distribution, migration, and seasonal occurrence of the various species Much of this information, but not the whole of it has been embodied in the ten reports published by Harmer From the beginning of his association with the Museum, Harmer also took a leading part in pressing on successive governments the urgent need for the regulation of the whale fisheries, particularly in the Antarctic His efforts were largely responsible for the organisation of the very important scheme of oceanographical research now being carried out by Dr Stanley Kemp and his staff for the 'Discovery' Committee, an undertaking which can only be compared in importance with the *Challenger* expedition

Prof W B Scott

THE Boston Society of Natural History has awarded the Walker Grand Honorary Prize of 500 dollars to Prof. William Berryman Scott, of Princeton, New Jersey, for 'his half century of conspicuous effort to advance the science of vertebrate paleontology in North America" Prof Scott is professor emeritus at Princeton University, where he held the Blair professorship of geology and palæontology from 1884 until 1930 He was born in Cincinnati, 1858, received his bachelor's degree from Princeton, Ph D from Heidelberg, LL D from the University of Pennsylvania, and honorary doctorates of science from Harvard and Oxford He is a past president of the Geological Society of America and the Paleontological Society of America, his specialty having been vertebrate palæontology He is the author of a well known geological textbook, also of the 'History of Land Mammals in the Western Hemisphere", and of the Theory of Evolution", and has written some fifty monographs on geological and palæontological subjects The Walker Grand Prize is awarded by the Society from the trust fund given by Dr William J Walker in 1864 not oftener than once in five years, for such scientific investigation or discovery in natural history as the Society may think deserving thereof, providing such investigation or discovery shall first have been made known and published in the United States The award is made solely for merit

Henry Francis Blandford, F R S (1834–93)

HENRY FRANCIS BLANDFORD, the distinguished meteorologist and geologist, brother of William Thomas Blandford (1832 1905) president of the Geological Society, was born in Bouverie Street Whitefriars London on June 3, 1834 Like his brother, he was trained at the Royal School of Mines under De la Beche Smyth and Percy and at the Mining Academy of Freiburg, and in 1855 with his brother joined the Geological Survey of India After serving for seven years ill health compelled him to resign from the Survey and he became a professor at Presidency College, Calcutta, a post he held from 1862 until 1874 From 1867 he was also meteorological reporter to the Government of Bengal, making a close study of cyclones, and in 1874 was appointed chief of the Meteorological Department of India Retiring in 1888 he took up his residence at Folkestone He died on January 23, 1893, at the comparatively early age of fifty eight years Elected F G S in 1862, and F R S in 1880, in 1884 he was elected president of the Asiatic Society of Bengal He wrote some fifty papers on meteorology and geology, and his work as a meteorologist caused him to be elected an honorary member of various foreign meteorological societies

Francesco Denza, 1834 94

ON June 7 the centenary occurs of the birth at Naples of Father Francesco Denza, the eminent Italian astronomer and meteorologist At the age of sixteen years, he joined the order of Barnabites and studied at Rome, where he came under the influence of Secchi, the astronomer From 1856 until 1890 he was attached to the Barnabite College at Moncalieri, where in 1859 he established an observatory Keenly interested in meteorology, he did much to further its study in Italy, founding the *Bollettino mensile di Meteorologia*, and in 1881 was chosen to be the first president of the Italian Meteorological Society He was also well known for his observations on meteors and his researches in terrestrial magnetism He represented the Pope at the Congress of Scientific Societies held in France in 1884, and again at the Paris Congress held in 1887 to inaugurate the Astrographic Chart of the heavens. Through him the Vatican Observatory was chosen as one of the eighteen observatories to take photographs for the preparation of the Chart, and in 1890 he was appointed as its director. He died at the Vatican on December 14, 1894, at the age of sixty years. He had been elected an honorary member of the Royal Meteorological Society in 1870, and at the time of his death was president of the Accademia dei Nuova Lincei.

Prof. Ernst Küster

PROF. ERNST KÜSTER, who has been for thirty-one years editor of the *Zeitschrift für Wissenschaftliche Mikroskopie*, has been elected to honorary fellowship of the Royal Microscopical Society. Prof. Kuster is professor of botany in the University, and director of the Botanical Institute and Gardens, Giessen. He was previously assistant in the Botanical Institutes at Munich and at Halle, professor of botany in the University of Kiel, and later in the University of Bonn. He is the author of "Pathologische Pflanzenanatomie" (3rd Ed., Jena, 1925), "Anleitung zur Kultur der Mikroorganismen" (3rd Ed., Leipzig, 1921), "Ueber Zonenbildung in kolloidalen Medien" (2nd Ed., Jena, 1931), and other botanical treatises, and of numerous scientific papers.

Economics of Nutrition

In the report of the Committee on Nutrition of the British Medical Association published last winter, the daily requirement of food was assessed at 3,400 Calories, and it was recommended that it should contain 50 gm. of animal or first class protein. These figures differed from those of the Committee of the Ministry of Health, which were 3,000 Calories and 37 gm. of animal protein. A controversy arose as to which set of data was correct. A conference of representatives of the two committees has since met and published a joint report (London: H.M. Stationery Office. 2*d*. net). The Ministry's Committee gave 3,000 Calories as a guide for the energy value for large communities and institutions. The figure of 3,400 Calories of the British Medical Association Committee was meant to apply to families with children with the man performing a moderate amount of muscular work, and to be subject to an allowance of 10 per cent for waste. As was stated in an article discussing the position in NATURE of January 13, p. 53, there is no real difference between the figures. The joint committee points out that no hard and fast line can be taken for differences in age and differences in work, and it gives a scale of Calories for different people. It is agreed that 80–100 gm. of total protein suffices for the daily need, the precise amount depending upon physique, occupation, habits, taste and climate. As regards the amount of animal protein, it is pointed out that there has never been any exact determination of the desirable proportion of animal to vegetable protein, and that 37 gm. is the lowest value obtained from statistics; 50 gm. is recognised as a good value for families with growing children, who need relatively more animal protein than adults.

Helium and Other Rare Gases

IN the second Research and Development Lecture delivered under the auspices of the British Science Guild at the Royal Institution on May 30, Lord Rutherford said that there is no more interesting story in the history of science than the sequence of events, towards the close of the last century, which led to the discovery and isolation of a new group of rare gases existing in the atmosphere by Lord Rayleigh and Sir William Ramsay. The discovery that argon is present in the air in about one per cent by volume was rapidly followed by the discovery of a whole new group of inert gases, namely helium, neon, krypton and xenon. Neon is present in the air in only about one part in 100,000 by volume, and helium, krypton and xenon are present in still smaller quantities. In the early stages, these gases could only be separated in small quantities after much expense and trouble, and in a sense were regarded as scientific curiosities. The subsequent development of large liquid air plants for the separation of pure oxygen from the atmosphere, in which many thousands of tons of air are liquefied annually, made possible arrangements for the separation of argon and neon in considerable quantities. On account of their characteristic properties some of these gases have been found exceedingly useful to industry. For example, more than 30,000 cubic metres of argon are used annually in Europe in the production of the highly efficient gas filled electric lamps. In all, about 45 million of these lamps are made each year, requiring the separation of argon from more than 5,000 tons of air. The ease with which an electric discharge passes through neon, and its characteristic luminosity, have led to a great development in the use of this rare gas for the illuminated signs with which we are so familiar in our cities to-day.

IN some respects, however, the history of the use of helium is still more striking. The presence of this gas was first detected in the sun by Sir Norman Lockyer in 1868 and for this reason he named it 'helium'. The presence of helium on the earth was first observed by Ramsay in 1895 in the gases released from old radioactive minerals. In the course of the next ten years, a few cubic metres of helium were laboriously extracted from radioactive minerals. During the War, the Board of Invention and Research of the Admiralty recognised that it would be much safer if observation balloons and dirigibles could be filled with a light, non-inflammable gas like helium rather than with hydrogen, for there is only eight per cent difference in their respective lifting powers. At the suggestion of the Board, Prof. J. C. McLennan, of the University of Toronto, made a systematic examination of the helium resources of the Empire. It was found that large supplies of helium were available in the natural gas fields of southern Alberta, and arrangements were made on a semi commercial scale to purify the helium by liquefying the methane and other gases present About the same time, the Bureau of Mines of the United States began similar experiments, using the natural gases of Texas, which are rich in helium At the end of the War, millions of cubic feet of helium were separated by liquefaction methods, and the cost was found to be sufficiently low to use it in airships in place of hydrogen The U S airships, the *Shenandoah* and the *Akron*, were both filled with helium to avoid the dangers of fire Apart from this and other industrial uses, helium is of great importance in the liquid form for attaining temperatures not far removed from absolute zero A number of cryogenic laboratories employing liquid helium are in active operation in Europe, Canada and the United States, for the study of the properties of matter near the absolute zero of temperatures

Congress of Anthropological and Ethnological Sciences

A PRELIMINARY programme of the first session of the International Congress of Anthropological and Ethnological Sciences to meet in London under the presidency of the Earl of Onslow from July 30 until August 4 next is now available The headquarters will be at University College, Gower Street, W C 2 The inaugural meeting will take place in the Great Hall of the College on July 30 at 3 p m , when H R H the Duke of York will receive the delegates and declare the Congress open, and Lord Onslow will deliver his presidential address On the same day at 10 p m H M Government will hold a reception of the members of the Congress at Lancaster House, St James's, S W The business of the Congress will be conducted in general and sectional meetings At the first of the general meetings, which will be held on July 31 at 8 30 p m , Sir Aurel Stein will deliver the Huxley Memorial Lecture of the Royal Anthropological Institute and will receive the Institute's Huxley Memorial Medal for 1934 At subsequent general meetings in the evenings of the following days the Congress will be addressed by Dr R R Marett, Prof T C Hodson, and Prof J B S Haldane, each of whom will deal with some one aspect of present tendencies in anthropological studies Communications addressed to the Congress by its members will be submitted to meetings of the sections, of which there will be eight, each one dealing with a major division of the studies with which the Congress is concerned

So far as it is possible to judge from this preliminary outline, the proceedings of the sections will be of the greatest interest In each section topics of inquiry are suggested, although members are not thereby necessarily precluded from submitting communications on other matters In the Anatomical and Physical Section, which will meet under Prof Elliot Smith, for example, the central theme will be man's place among the primates In most sections, however, the range is sufficiently wide to cover all points which members are likely to have time or desire to discuss Joint meetings between two or more sections occupy a prominent place in the programme The Section of Ethnography, which, naturally, is expected to have the heaviest list of communications, will meet in three divisions, General Ethnography under Dr A C Haddon, African Ethnography under the Rev E W Smith and American Ethnography under Capt T A Joyce The last named sub section has been specially arranged with the view of welcoming American workers on their way to attend the International Congress of Americanists to be held later at Seville It will take as its central theme of discussion the interrelation of pre Spanish American culture centres and their possible connexion with extra American influences, affording it is hoped, a welcome opportunity for placing on record the results of the most recent developments in research In the African Section current problems impinging on questions of administration and the future development of the African will be kept well in view The subscription to the Congress is members £1, associates 10s Further particulars may be obtained from the Congress Secretaries c/o the Royal Anthropological Institute, 52 Upper Bedford Place, London, W C 2

Japanese Trade Competition

JAPANESE competition in the world s markets is more than a new and noteworthy fact Discussing the matter in a recent issue of the *Industrial Chemist*, Sir Harry McGowan chairman and managing director of Imperial Chemical Industries, Ltd , shows that by no means the whole story involves the long hours of work and the low standard of living of the Japanese worker , contributory aids to Japan s advance are her realisation that in times of depression, price is more important than quality, and her study of the needs of individual markets Her manufacturers give each customer what he wants at the time and place that it is wanted, and patterned, designed, and packed in a manner to please his particular fancy They quote in his own language and express units of quantity and price in the measurements of his country ' Japan needs to sell goods abroad to maintain some equilibrium in her trade balance, to support her rapidly growing population, and to pay for her increasing armaments She has the advantage of a considerably depreciated currency , a newcomer into the industrial arena, she has bought the most up to-date machinery and adopted the most suitable methods, and she has organised her industries in large scale units She has evolved a system of industrial and governmental co-operation in the conduct of export campaigns Sir Harry McGowan counsels us to take prompt and vigorous steps to put ourselves so far as possible on a competitive basis We will not, and indeed cannot, depress the standard of living of our work people, but we can reap the advantages of industrial organisation and the effective planning of export trade The time has come for closer personal contact between British and Japanese industrialists, and for discussion which will lead to a tempering of healthy competition with reasonable co-operation

Reclamation of the Pontine Marshes

IN the *Engineer* of May 11 and 18 is an illustrated account of the work being done in connexion with the reclamation of the famous Pontine Marshes in southern Italy This work has been rendered possible by the passing by the Italian Government of the law of the Bonifica Integrale', commonly known as the Mussolini Law, 1928, which authorised the expenditure of 7,000 million lire (£113,000,000) for works of public utility such as irrigation and water supply schemes, roads, and reclamation projects 'Among these great works of agricultural reconstruction," says the *Engineer*, "the reclamation of the Pontine Marshes deserves particular attention, not only on account of their geographical position almost at the doors of Rome (40 miles distant), and of their history, but above all from a technical point of view, as it is the first time in history that a similar vast enterprise has successfully been carried out, and that a flourishing town—Littoria—has, magic like, risen within thirteen months from its inception on what were the pestilential malaria stricken and deadly Pontine Marshes" The area of the marshes, across which once ran the Via Appia, is some 60,000 acres, and its reclamation had been discussed from the days of Caesar to Napoleon But it remained a blot on the prestige of Italy In 1926, however, a scientific survey of the district, its rainfall and geology, was carried out and each succeeding year has seen the construction of canals for drainage or irrigation, the erection of pumping and power stations, the clearing of woods, the breaking up of the soil and the settlement of some thousands of people on the recovered land The colonisation of the area is being carried out by the Opera Nazionale Combettenti (National Ex Service Men's Organisation) which provides each family of colonists with a house, live stock and fodder, implements, seeds, etc, guarantees to pay for produce at market price and arranges easy terms of purchase By October 1935 it is considered the scheme will see the colonisation of about 5,000 families, representing a population of 50,000

River Water Survey

THE forty first annual report of the West Riding of Yorkshire Rivers Board for the year ended March 31 covers an extensive area, embracing, in part or in whole, the basins of the Lune, Ribble, Ure, Nidd, Wharfe, Aire, Calder, Don and Trent, therefore it naturally comprises a number of scientifically interesting, though miscellaneous, items of information, which cannot be effectively summarised within brief compass As the twelve months in question coincided with the prevalence of the abnormally dry season which has made a shortage of water unpleasantly felt throughout Great Britain, it is not surprising to learn that "for extraordinarily lengthy periods the flow of the main rivers passing through the thickly populated manufacturing areas dwindled to about half the normal volume and a very large proportion of the water consisted of compensation water and effluents from sewage works and trade premises" The Aire and the Calder, it is stated, continue to be the worst polluted streams in the West Riding, but the sources of pollution have become more and more localised as the work of the Board has proceeded. On the subject of excessive river pollution following sudden heavy downpours after long spells of dry weather, the explanation is put forward that during dry weather the whole flow of sewage can be fully treated at sewage works, and during continuously wet weather the dilution afforded by the streams is sufficient to obliterate the effects of the discharge of storm water sewage and surface water drainage, but that a heavy shower in dry weather may carry intense pollution into a depleted river An analysis is given of a sample of river water from the Calder at time of maximum flow after heavy rainfall, demonstrating in a striking way the intensive wave of pollution set up under such conditions

REFERENCE is made in the report to the important matter of river gauging, and it is stated that consistent attempts have been made to persuade local authorities to take a greater interest in the work and to co operate in extending activities over a greater number of streams It is satisfactory to find that these efforts have been attended by some degree of success, though the report adds "it has required the rather alarming experiences of the droughts of 1929 and 1933 to make it evident that a comprehensive scheme of stream gauging is one of the essentials in regard to a systematic survey of the country's water resources" The action of the British Association in appointing a committee to investigate the question of an inland water survey is sympathetically alluded to, and it is stated that the Board has been asked by the Institution of Civil Engineers to co operate in the movement by allowing its records of river gaugings to be made available for inclusion in a comprehensive survey which the Institution has in contemplation (see NATURE of Nov 11, 1933, p 725, and April 28, 1934, p 625)

Food Supply and Public Health

IN his Chadwick Public Lecture delivered on May 29, Dr John Boyd Orr discussed the national food supply and public health He stated that, if necessary, Great Britain, which at present imports about half of its foodstuffs, could increase production sufficiently to become self supporting Between 1913 and 1928, the world's food production increased by 16 per cent, whereas the population of the world increased by only 10 per cent But the amount of food a person can eat is limited, and in the case of some products, notably wheat, production has outrun consumption In 1932, the world's requirement in the international wheat market was 525 million bushels, whereas the exportable surplus of the great wheat producing countries was 1,105 million bushels. The problem with regard to the supply of certain foodstuffs is now, not how to secure a sufficient supply, but rather how to dispose of the surplus, which is encumbering the world economic system Governments are attempting, through international conferences, to evolve schemes to limit production.

This super abundance of certain stable foodstuffs has led to a cheap food supply for the people—at least for certain kinds of food Unfortunately, those foodstuffs which have a special health value are still relatively expensive At present retail prices, 3,000 Calories, roughly the amount required by an average man, can be obtained in the form of certain foodstuffs, for example, white bread, rice, sugar, margarine, for *3d*–*5d* , but the same number of Calories costs about *2s* in the form of milk, *3s*–*5s* in the form of vegetables, *4s* in the form of eggs, and *1s*–*3s* in the form of meat Production of these more expensive foodstuffs is increasing in efficiency with a corresponding fall in wholesale prices Distribution, however, is still relatively inefficient and expensive and schemes for the marketing of agricultural produce are now being undertaken

Suppression of Weeds

OUR knowledge in the use of artificial fertilisers has now become very extensive, and a great deal of information has also been acquired with regard to the destruction of weeds by chemical means Further, certain fertilisers have a two fold value in that they act as weed destroyers as well as encouraging the growth of the crop Spraying for weed eradication was introduced in France towards the end of last century, when copper sulphate was used to kill charlock and wild radish The practice soon became widespread and at the present time the use of sulphuric acid is rapidly becoming a recognised means of destroying various annual weeds in cereal crops, as is also the fertiliser cyanamide, while chlorates seem likely to attain a position of importance in the future for the destruction of particular weeds in certain circumstances Mr H C Long of the Ministry of Agriculture has just published a simple and concise account of the subject in a brochure entitled The Suppression of Weeds by Fertilizers and Chemicals ' The use of lime calcium cyanamide, sulphuric acid, sulphates of copper and iron, chlorates and arsenical compounds are the substances chiefly dealt with, and recommendations for the destruction of many weeds that commonly occur in serious quantities are described The booklet extends to 57 pages, and includes 17 photographic illustrations and 5 line drawings It may be obtained from the author at 'The Birkins", Orchard Road, Hook Surbiton, price *2s* net (by post *2s 2d*)

Sociological Studies

Two reports in the Special Report Series ' of the Medical Research Council, recently issued (London H M Stationery Office), are of considerable, though somewhat specialised, interest No 190, A Study of Growth and Development", by Miss R M Fleming contains a record of observations in successive years on the same children, with continuous observation on a number of anatomical characters, and an attempt to relate to them psychological characters of the growing individuals and their reactions to the physical and psychical environments in which they lived No 192, "Housing Conditions and Respiratory Disease", by Dr. C M Smith, deals with the amount, nature and incidence of sickness occurring during one year among a population of two thousand people living in a poor quarter of Glasgow, one half being housed in a slum type district, the other half in a rehousing scheme area Comparison of the morbidity in the two groups does not yield conclusive results, and the value of the work lies rather in indicating the fallacies and difficulties involved in reaching reliable conclusions in investigations of this kind

Blindness

SIR JAMES BARRETT has prepared an analysis of the causes of their blindness in applicants for admission to an Institute for the Blind (*Med J Australia*, 1933, December 30, p 872) Among those over fifteen years of age, myopia (short sightedness) heads the list with 15 per cent of the total Of all cases, venereal diseases probably cause 40–50 per cent In another paper in the same journal (July 15 p 69), Sir James gives an account of the development of the Braille system Introduced in 1834, various modifications were attempted, so that at the end of last century there were several kinds of Braille in the English speaking world In 1905, Great Britain decided to adopt Braille uniformly , about the same time the Americans appointed examiners to inquire into the various Braille systems, and in 1913 they reported that the original Braille system came out of the test as the best, and it was adopted in America in 1918

Crocodiles and Alligators

A NEW part of Das Tierreich by Dr Franz Werner of Vienna (Pp xiv+40 Berlin and Leipzig Walter de Gruyter and Co 8 75 gold marks) deals with Reptilia Loricata and contains keys and short descriptions of the distinguishing characters of gavials, crocodiles and alligators, as well as short notes on colour, habitat and distribution The characters selected as discriminating are readily appreciated and the descriptions are helped by 33 text figures Old names are changing , the once familiar *Crocodilus niloticus* has become *Champse vulgaris*, and as a generic name *Crocodylus* is, paradoxically, confined to two alligators from South America, one of which is named *Crocodylus niloticus* —a native of British Guiana, Bolivia and that region ! This and other points are referred to in a letter on p 835 of this issue

Investigations of Rudi Schneider

IN the article 'From a Correspondent" on MM Osty s investigations on Rudi Schneider in our issue of May 19, p 747, the importance of an independent repetition of these experiments is urged Prof D F Fraser Harris writes to direct attention to the investigations of Lord Charles Hope and others published in the *Proceedings of the Society for Psychical Research* of June 1933 These experiments, however, did not include any graphs of the rhythmic obscuration of an infra red ray in time with Schneider's breathing, to which our correspondent specially referred

Tenth Satellite of Jupiter

ACCORDING to *Science Service*, Dr H M Jeffers of the Lick Observatory photographed a very faint object (of the nineteenth magnitude) which appears to have the same motion in the sky as the eighth satellite of Jupiter The new satellite has presumably a diameter even smaller than that of the eighth, which is only 25 miles If the new object's identity as a satellite of Jupiter is established that planet will lead the field as a satellite holder, Saturn having but nine Jupiter is now very prominent in the evening sky, and the four brightest satellites can be seen with a modest telescope But for the glare from the planet they should just be visible to the naked eye in a good climate (It has been stated that certain Kalahari natives *can* distinguish Jupiter s satellites with the naked eye) With the most powerful telescope, however, nobody will *see* the new satellite of the nineteenth magnitude It can only be photographed by giving fairly long exposures on a large telescope

Announcements

MAURICE, DUC DE BROGLIE has been elected to a seat in the Académie Française the section of the Institut de France which concerns itself with language and literature M de Broglie is well known as a physicist for his work on X ray spectra and allied subjects, for which he was awarded the Hughes Medal of the Royal Society in 1928 For the past ten years he has been *académicien libre* of the Académie des Sciences, which is the scientific section of the Institut de France

THE second conversazione this year of the Royal Society will be held at the Society s rooms on June 20 at 9 p m

IT is announced in the *Times* that Sir Charles Brooke, Rajah of Sarawak, has given £20 000 towards the building scheme for the Imperial Forestry Institute at Oxford

THE research laboratories of the Callenders Cable and Construction Co , Ltd , 38, Wood Lane, Shepherd's Bush, London, W 12, will be opened by Lord Rutherford on Friday, June 22

THE annual general meeting of the British Science Guild will be held in the lecture theatre of the Royal Society of Arts on Tuesday, June 12, at 4 p m Following the meeting, a popular lecture entitled Friction" will be delivered by Prof E N da C Andrade

AT the anniversary meeting of the Linnean Society of London held on Thursday, May 24, the following officers were elected —*President* Dr W T Calman, *Treasurer* Mr F Druce, *Botanical Secretary* Mr John Ramsbottom, *Zoological Secretary* Dr Stanley W Kemp The Linnean Gold Medal was presented to Sir Sidney Harmer

THE secretary of the University Press of Liverpool, referring to the notes on the centenary of the Liverpool Medical School in NATURE of May 19, p 753, asks us to state that The Liverpool Medical School 1834–1934" is the production of the University Press, and is published by the Press, with Messrs Hodder and Stoughton, Ltd

UNDER the title of 'The Silk Industry of Japan" the Imperial Council of Agricultural Research (India) has issued (1933) a comprehensive monograph by Mr C C Ghosh on this subject It is primarily based upon the results of a study made by Mr Ghosh in Japan in 1929 and provides a useful illustrated account of the biological, technical and administrative aspects of the industry The work can be obtained through booksellers, or through the Office of the High Commissioner for India, Aldwych, London W C 2, price 6*s* 9*d*

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A lecturer in physics and elementary science (including nature study) at the City of Leeds Training College—The Director of Education, Education Department, Calverley Street, Leeds (June 5) A teacher of physical chemistry at the Northern Polytechnic Holloway London, N 7—The Clerk (June 6) An assistant professor and a lecturer in mathematics at the Royal Naval College, Greenwich —The Adviser on Education Admiralty, Whitehall, S W 1 (June 11) A lecturer in mathematics at the Constantine Technical College—The Director of Education, Education Offices, Middlesbrough (June 9) A temporary assistant lecturer in agricultural botany at the University College of North Wales, Aberystwyth—Prof R G Stapledon Agricultural Buildings, Alexandra Road, Aberystwyth (June 12). A lecturer in chemistry at the Medway Technical College, Gardiner Street, Gillingham, Kent—The District Education Officer, 15 Mew Road Avenue, Chatham (June 16) A part time assistant (biology) in the Department of History and Method of Science at University College, Gower Street, London, W C 1—The Secretary (June 16) A lecturer in political science at the London School of Economics and Political Science, Houghton Street, Aldwych, W C 2 —The Secretary (June 22) Examiners in various branches of science in the University of London—The External Registrar, University of London, South Kensington, S W 7 (July 8) A professor of mining and a professor of geology in the University of the Witwatersrand, Johannesburg—The Secretary, Office of the High Commissioner, South Africa House, Trafalgar Square, London, W C 2 (July 14) A senior lecturer in psychology, a lecturer in geology and a lecturer in mathematics (at Pietermaritzburg) and a lecturer in civil engineering, a lecturer in mathematics and chemistry and a lecturer in English and psychology (at Durban) in Natal University College—The Registrar, Natal University College, Pietermaritzburg (Aug 1) A technical adviser on industries to the Bureau of Industry and Commerce, Ceylon—The Crown Agents for the Colonies, 4, Millbank, London, S W 1

Letters to the Editor

Arbitrary Character of World-Geometry

PROF E A MILNE, in the important paper[1] in which he gives an account of an invariant distribution of particles forming an expanding universe in flat space time, has stated that the geometry adopted in cosmological theories may be chosen arbitrarily, the expression of the laws of Nature being relative to the geometry assumed A similar view has also been expressed by myself[2] The first enunciation of the idea, however, seems to have been due to Poincaré in quite the early days of relativity It is interesting in this connexion to observe that there is a very simple method of converting the law of motion of a particle expressed in the geometry of Einstein's theory to the corresponding law expressed in any other geometry

In general relativity the world line of any particle is a geodesic, a four dimensional track satisfying the principle

$$\delta \int ds = 0, \qquad (1)$$

where

$$ds^2 = \sum_{\mu\ \nu} g_{\mu\nu}\, dx_\mu\, dx_\nu$$

The g's are here functions of x_1 x_4 which when given fix the geometry of the manifold, the x s being arbitrary Gaussian co-ordinates, may be assumed to be the space and time measures of some (usually specially defined) observer Multiplying by a dimensional constant and, top and bottom, by the element $d\sigma$ of any parameter we can write the geodesic principle as

$$\delta \int m \sqrt{\sum g_{\mu\nu} \frac{dx_\mu}{d\sigma}\frac{dx_\nu}{d\sigma}}\; d\sigma = 0 \qquad (2)$$

But in this form the equation can be interpreted in *any* geometry Thus if $d\sigma$ is the interval of any specified fourfold, (2) becomes a principle of stationary action in that fourfold,

$$\delta \int W d\sigma = 0, \qquad (3)$$

where W, the weighting function of $d\sigma$, is, with given g s, a known function of the co ordinates and direction cosines of the (now curved) track at each point Or if in (2) we write for σ the t of flat space time, we have Hamilton's principle direct,

$$\delta \int L dt = 0,$$

with the Lagrangian L a known function of co ordinates and components of velocity From this the motion in ordinary space of the particle is obtainable in the usual way

The philosophic implications of such a conversion are considerable The motion of a particle being described generally as a track of stationary action (of a ray of light, zero action), in

$$\delta \int dA = \delta \int \frac{dA}{d\sigma}\, d\sigma = 0$$

the invariant element of action dA may be factorised in arbitrary ways into action gradient $dA/d\sigma$ and interval $d\sigma$ The latter fixes the geometry and the former is the weighting function W in (3) The physicist working on classical lines naturally adopts the simplest geometry, flat space time, throwing the burden of accounting for non uniform motion on the weighting function, which describes in effect a 'field of force' The relativist, going to the other extreme, throws the whole burden on the geometry But though these extreme ways are the simplest the burden clearly can be distributed arbitrarily between W and $d\sigma$, these being adjustable co factors of the more fundamental thing, action Action itself, comprising them both, transcends the ideas of geometry

In a paper published some years ago[3], I have shown that the electromagnetic laws also can be expressed by a principle of stationary action,

$$\delta \int dA = \delta \int \frac{dA}{dV}\, dV = 0,$$

where dV is a four dimensional volume element in the field The electromagnetic field, therefore, like the gravitational, is obtained by a factorisation of action, but now made differently, the co factors being action *density* and *volume* element The former of these effectively specifies the field, for in flat space time

$$\frac{dA}{dV} \equiv \tfrac{1}{2}\{(e^2 - h^2)^2 + 4(eh)^2\}^{\frac{1}{2}}$$

Since dV, like $d\sigma$, can be used to define a type of geometry, the feature of arbitrariness in the geometry assumed applies to both classes of field

Maximum Optical Paths

ERRORS that have once appeared in print have a way of turning up in the most unexpected places As Dr Karl Darrow's interesting article on quantum mechanics in *Review of Modern Physics*, 6, 23 January 1934, is sure to be very widely read in Great Britain, it is not inopportune to refer to an old mistake that he repeats He states that optical paths are routes sometimes of minimum and some times of maximum time, and that for this reason it is appropriate to refer to them simply as stationary paths His foundation is wrong though his conclusion is right The facts are that the time happens to be a minimum when the path does not include an image of an end point of the range considered, but that if the path includes such an image, the time is neither a maximum nor a minimum—it is simply stationary Thus in Fig 1, if A', the image of A, is an internal point of the path interval APB, so that the optical

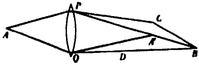

FIG 1

lengths APA' and AQA' are equal, the path $APCB$ is obviously longer and the path $AQDB$ obviously shorter than the stationary path $APA\ B$ It is clearly a trivial matter to demonstrate that no given optical path is ever a maximum

The error perhaps arose from a mistaken attempt to illustrate the alternate occurrence of maxima and minima by the various optical paths between the two foci of an elliptical mirror, and its currency is doubtless due to the fact that the coincidence in space of the object and image fields for reflection makes confusion of thought particularly easy It

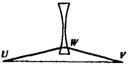

Fig 2

must be emphasised that the direct path, and paths including reflection at the mirror relate to different sets of conditions, and they should no more be confused than the direct path from U to V represented in Fig 2 should be confused with the refracted path UWV In refraction the distinction between the object and the image spaces is usually forced on a student's attention by the experimental conditions In reflection the importance of maintaining a similar distinction in his mind has to be forced on a pupil's mind by his instructor

Plasticity of Bismuth due to Occluded Gas

BISMUTH crystals in the form of wires are described by Georgieff and Schmid[1] as being ductile if the (111) plane makes an angle $\varphi < 55° 42$ with the axis of the wire If $\varphi > 55° 42$, their crystals are brittle The ductility is due to slip along the (111) plane which is also the breaking plane of their crystals Gough and Cox[2], however, do not find any ductility due to slip of bismuth crystals of any orientation The only type of deformation of their crystals consists of twinning on planes of type (110)

The various attempts to explain this discrepancy[2] do not seem to take account of the fact that different methods are employed by the different authors to make the bismuth crystals concerned Georgieff and Schmid apply the Czochralski method, in which the liquid metal is raised, by means of a glass capillary out of a hole in a lid which covers the heated crucible and floats on the molten metal The rising metal is cooled by means of a stream of gas as it comes out of the lid Crystals of the diameter of the hole and of any length, can thus be obtained Gough and Cox apply the Bridgman method in which a cylindrical mould with tapering ends, filled with molten metal and carefully evacuated, is lowered slowly through a vertical tubular furnace Both methods have the common feature that a temperature gradient in a certain direction is achieved which makes the crystal grow in this direction

To check these results, both methods of making metal crystals were applied The bismuth used was Bi, purified" supplied by Hopkin and Williams, Ltd, London The cooling gas was nitrogen from a steel cylinder Some of the crystals obtained by the Czochralski method were brittle and some were ductile, and the latter showed after extension clear slip lines parallel to the (111) plane The brittle crystals showed twin formation when a tensile test was applied, giving audible 'cries', but no appreciable elongation So far, the results are in agreement with those of Georgieff and Schmid

None of the crystals obtained by the Bridgman method showed slipping in tensional tests, even when the (111) plane was suitably orientated for slipping They always broke along one of the other planes of (111) type, at normal stresses ranging from 337 to 712 gm/mm^2 (Accurate figures cannot yet be given owing to the lack of a suitable tensile machine) Profuse twinning sometimes occurred before breaking, accompanied by audible sounds (In compression tests however, even the crystals made by the Bridgman method exhibit slip Cylindrical rods become noticeably thicker in the direction perpendicular to the (111) plane and show clear slip lines There is no discrepancy here with the results of Gough and Cox as they use cycles of stress and therefore cannot apply forces bigger than the breaking force)

The explanation I suggest is that the crystals made by the Czochralski method contain a certain amount of the gas which is used for cooling The gas is responsible for the slipping of bismuth in tensional tests

To check this Czochralski crystals were heated *in vacuo* to about 600° C One could observe a large amount of gas coming out of the metal just after the melting point was passed The amount was estimated by measuring the pressure in a part of the diffusion pump set which could be separated from the pump and the volume of which was known Moisture was frozen out by means of a liquid air trap It was thus found that the single crystal contained about 3×10^{-4} molecules of nitrogen per atom of bismuth

Although every precaution was taken—for example the crystals were not touched by hands at all—this figure should be regarded with some reserve until further experiments check it fully But it seems to be certain that the content of gas is responsible for the slipping of a suitably orientated bismuth crystal in tensional tests

A Magnetic Effect on Pirani Gauges using Nickel Wires

A PAIR of sensitive Pirani gauges, set up in this laboratory for another purpose, was found to be remarkably sensitive to small magnetic fields It seemed worth while to give a report of the phenomenon which may be of interest to those working in the field of thermomagnetic effects The gauges consist each of a thin nickel strip, 12 cm long and 0 003 mm by 0 05 mm in cross section They are mounted parallel and about 2 cm apart in a high vacuum, and are connected in two of the arms of a Wheatstone bridge, the other two arms being fixed resistances

A relay magnet about 6 cm away from the gauges (in the plane containing both wires) was found to produce a large deflection of the bridge galvanometer when energised The amount of the deflection depends strongly on the voltage across the bridge (that is, on the temperature of the nickel strips) The nature of the variation is shown in Fig 1 The abscissæ give the bridge voltages, with a rough scale of corresponding temperature, the ordinates give a quantity from which the bridge constants have been eliminated, and which represents the proportional change of resistance of one wire necessary to produce the observed deflection Since the effects in the two gauges are opposed, the actual change must be greater If the effect is thought of as a change in potential along the wires, the same quantity gives the proportional change of potential In the curve marked *A*, the line joining the poles of the magnet was placed perpendicular to the wires, in *B* parallel The peak in the curves occurs at or near the magnetic transition of nickel

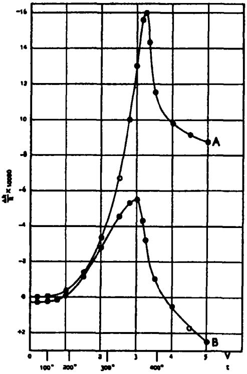

FIG 1 Magnetic effect on Pirani gauges plotted as equivalent relative resistance change against voltage across gauges and wire temperature Curve *A* magnet perpendicular to wire curve *B* parallel Note that curve *B* changes sign twice The peak in *B* may easily be caused by the superposition of some of the transverse effect

The effect is complicated by the presence of the residual field from a large electromagnet near the gauges This means that the field of the relay magnet must be considered as only a small change in an already existing field The geometrical relations are also too complicated for these results to be more than a rough picture of the phenomenon

The behaviour of the deflection on reversing the magnet current, reversing the bridge current, or putting the magnet near the other of the pair of wires, was just as would be expected if the effect were a simple change of resistance But the magnitude and the variation with temperature are widely different from the results of Knott[1] on nickel It is more likely that the effect is connected with the existence of a temperature gradient between the centre and the ends of the wires, being perhaps a change of the Thomson coefficient produced by the magnetic field Such a change is known to exist, but has apparently not been studied as a function of temperature

Gaugain-Helmholtz (?) Coils for Uniform Magnetic Fields

THE use of two equal and co axial circular coils of wire, separated by a distance equal to their common radius and traversed by the same electric current in the same sense, has long been the standard practice for producing a nearly uniform magnetic field throughout an appreciable volume The question which seems unsettled is whether Helmholtz improved upon a device invented by Gaugain or invented the whole device by himself at an earlier date

In favour of the latter point of view is the statement by Wiedemann in 1883 (in a footnote to p 250 of the third volume of his 'Lehrbuch der Elektrizität") "Helmholtz hat das Princip dieser Bussole schon in der Sitzung der physikalischen Gesellschaft zu Berlin am 16 März 1849 mitgetheilt und zu derselben Zeit einen Apparat nach diesem Principe construirt und benutzt" I have not been able to find any other report of this session except the title of the lecture 'Princip bei der Construction der Tangentenbussolen' This, with the date, is given in *Fortschritte der Physik im Jahre 1849* (p vii)

In favour of the former point of view is the absence of any reference to Helmholtz either in the papers of Gaugain (*Comptes rendus*, 36, 191–193 *Ann d Physik*, [2], 88, 442–446, 1853 *Ann de chim et de phys*, [3], 41, 66–71, 1854) or in the supporting note by Bravais (*Comptes rendus*, 36, 193–197 *Ann d Physik*, [2], 88, 446–451, 1853) Furthermore, we have the much quoted statement by Clerk Maxwell 'Helmholtz converted Gaugain's galvanometer into a trustworthy instrument by placing a second coil, equal to the first, at an equal distance on the other side of the magnet' ("Treatise on Electricity and Magnetism", vol 2, p 318, 1873, 2nd ed, vol 2, p 327, 1881, 3rd ed, vol 2, p 356, 1892) This, it will be observed, considerably antedates Wiedemann's note on the subject Helmholtz, so far as I can find, made no claim on his own account at any time

A less direct but even more convincing argument in favour of Gaugain's priority is furnished by the following facts F E Neumann, a great authority on Ampère's discovery and its applications, was at Königsberg when Helmholtz went there in 1849, so that they were colleagues during the period when, if ever, Helmholtz anticipated Gaugain We learn from a paper by H Wild (*Vierteljahrsschr d naturf. Ges in Zürich*, 2, 239, 1857) that Neumann lectured on two-coil and four-coil combinations at least as early as 1856 In a transcript of Neumann's

Vorlesungen über elektrische Ströme", as given in 1864–65, published with his permission in 1884 by K Vondermühl, we find on p 197 a careful reference to Gaugain (the only reference in a 36 page chapter) and no mention of Helmholtz

This letter is written in the hope that some reader of NATURE may have additional evidence to offer If none is forthcoming, I think we should call the two coil combination Gaugain Helmholtz coils If the whole truth were known, it seems probable that the proper designation would be Gaugain Neumann

The Apparent Thermionic Constant *A* of Clean Metals

THERE seems to be little room for doubt that the apparent thermionic *A* (the *A* derived from a Richardson line) of at least some clean metals is genuinely less than the upper theoretical limit for this quantity, A_0 the value of which is 120 amp cm^{-2} deg^{-2} Thus, for tungsten, tantalum and molybdenum, which are among the metals for which the most reliable data are available, values of 60 100, 60 and 55 amp cm^{-2} deg^{-2} respectively have been obtained, and, if surface roughness had been taken into account, somewhat smaller values still must have been found It would, of course, be quite possible to attribute these results to an imperfect transmission of the electrons through the emitting surfaces, assuming the apparent *A* to be the true *A* There is however, a known effect which, unless compensated for by other effects, must make the apparent *A* less than the true *A* by a factor of at least 2 or 3, and which would therefore, account for the order of magnitude of the observed data on the assumption of practically perfect transmission

It is well known that the apparent *A* will differ from the true *A* if the work function χ varies with the temperature According to Sommerfeld's theory of metals, this quantity is given by the equation

$$\chi = C - \frac{h^2}{8m}\left(\frac{3n}{\pi}\right)^{2/3},$$

where C, h m and n are the product of the inner potential and the electronic charge, Planck's quantum of action, the electronic mass, and the number of effectively free electrons per unit volume of the metal respectively Strictly speaking, there should be a further term in the expression for χ, but with ordinary free electron concentrations this is small and its temperature dependence makes the apparent *A* differ from the true *A* by only something like 2 per cent Apart from this, χ might vary with the temperature, as Fowler[1] has pointed out, owing to a temperature variation either of C or of n Concerning what variation of C with temperature is to be expected, little, unfortunately, seems to be known There must, however, be a temperature variation of n associated with the thermal expansion of the metal, if, as is probable, the number of free electrons *per atom* remains constant. It appears worth while, then, to see whether the experimental data might be accounted for by assuming that C is sufficiently nearly constant for the temperature variation of χ to be determined in direction and order of magnitude by that of n alone

Let the coefficient of linear expansion be denoted by α Then from the formula for χ we find that the corresponding factor, f, by which the apparent *A* must be less than the true *A* is given by

$$f = \exp\left\{\frac{h^2\alpha}{4mk}\left(\frac{3n}{\pi}\right)^{2/3}\right\}.$$

In the temperature regions where thermionic measurements are usually made α has the value 6 3$\times 10^{-6}$ deg^{-1} for tungsten and 8 0$\times 10^{-6}$ deg^{-1} for both tantalum and molybdenum On the assumption of one free electron per atom the values of n for the three metals in the order named would be 6 2$\times 10^{22}$, 5 6$\times 10^{22}$ and 6 3$\times 10^{22}$ per cm^{3} respectively Hence for the corresponding values of f we should have 2 3, 2 7 and 2 9 respectively For two free electrons per atom we should have, instead, 3 7, 4 3 and 4 6 respectively These are of the order of magnitude of the factors by which the apparent *A* values fall short of A_0

Isomeric Nuclei?

As I have shown elsewhere[1], the introduction of negative protons into nuclear structure leads to the possibility of the existence of isomeric nuclei, that is nuclei with the same atomic number and atomic weight but different internal structure (a pair of positive and negative protons instead of a pair of neutrons) As an example the nucleus of uranium Z was given, which seems to be isomeric with uranium X_2

A further indication is furnished by recent measurements of Aston[2], who has found in the mass spectra of ordinary lead the line 210 This isotope of lead has the same atomic number and atomic weight as radium D but, since it exists to the extent of 0 08 per cent, it cannot be, of course, the usual radioactive radium D Therefore, if the ascription of the observed line to lead is not erroneous, we must conclude that the nucleus with atomic number 82 and atomic weight 210 may exist in two modifications (isomers) of which one is stable and the other is subject to β decay

Ground State of C_2 and O_2 and the Theory of Valency

ACCORDING to the quantum mechanical theory of the chemical bond in its original form, the lowest state of a diatomic molecule should be a singlet term The ground states of C_2 ($^3\Pi_u$) and O_2 ($^3\Sigma_g^-$) found experimentally seem to be in contradiction with this theory while other considerations (Hund, Mulliken, Lennard-Jones) lead to the right result

But it can be seen that the above mentioned theory also easily explains the experimental facts One has only to take into account that the binding energy of the molecule is not only due to the interaction of the ground states of the atoms, but is also effected by slightly excited atomic states For C_2 and O_2 one has to consider besides the ground states (^3P) the ^5S state of C and ^1D of O

It is well known that two potential curves with the same symmetry interact strongly if their separation is not too large In this case they repel each other so that one of the curves is strongly depressed and becomes very low

For C_2, the configuration $^3P - {}^3P$ (both atoms in the ground state) gives rise to singlets and triplets one should expect the lowest to be a singlet But from the configuration $^3P - {}^5S$ (one atom excited) only triplets result Therefore, because of the above mentioned interaction, just the triplet terms will be depressed By Slater and Pauling s method concerning the overlapping of eigen functions it can be seen that the strongest interaction exists between the two $^3\Pi_u$ terms So one of them becomes very low and a rough calculation shows that it probably lies still lower than the $^1\Sigma_g^+$, the lowest of the $^3P - {}^3P$ configurations, so as to become the ground state of the molecule in agreement with experiment

The same considerations can also be applied to O_2 From the configuration $^3P - {}^1D$ only triplet terms result The $^3\Sigma_g^-$ terms have the strongest interaction giving the fundamental state of the molecule[1]

Pupation of Flies initiated by a Hormone

Dr V B Wigglesworth reported in Nature of May 12 on the detection of a hormone which initiates moulting and pupation in a tropical bug In the pupation of flies a very similar principle is acting according to experiments carried out by me during the past few months Prepupæ of the blow fly *Calliphora erythrocephala*, were ligatured securely into two parts If the ligature was laid down not more than about 12 hours before pupation, both parts pupated, the anterior part preceding the posterior part usually by 1 to 3 hours But if the prepupæ were ligatured more than 12 hours before pupation, then either the anterior pupated alone, within 12 to 48 hours or both parts failed to pupate

In the fly larvæ all the ganglia are concentrated in a single mass in the anterior part of the body, so that by ligaturing, the posterior part is disconnected from the nervous centres It is, therefore shown that the separation of the nervous centres does not prevent the posterior part from pupating, if the separation took place only a short time before pupation From these experiments it can be concluded that something in the anterior part initiates or induces the pupation The isolated posterior part is able to pupate only if the induction by the anterior part was already accomplished before the ligature was laid down

This induction may consist of a nervous stimulus, brought to the skin by the nervous system, or it may be accomplished by a special hormone, secreted in the anterior part and carried about in the body by the blood The following experiments show that the latter alternative is the true one:

(1) Prepupæ are securely ligatured more than 12 hours before pupation and the ligature is taken away after about 15 min In these specimens the nervous conduction between the two parts of the body is interrupted but the blood circulates through the whole body When pupation takes place, it occurs in the whole body simultaneously

(2) The blood of prepupæ which are about to pupate is injected into posterior parts of younger prepupæ the anterior part of which was ligatured off about 24 hours before These posterior parts would never have pupated without the injection Of the injected posterior parts about 50 per cent pupated In certain cases they pupated only when a second injection was given 24 hours after the first

The localisation and identity of the organ which produces the hormone are being investigated

Crossing-over in the Land Snail *Cepæa nemoralis*, L.

A genetic situation of particular interest from the point of view of the evolutionary modification of genetic phenomena occurs, not only among fishes (*Lebistes*, and other genera) but also among insects (Orthoptera) and land snails (*Cepæa*) in all of which a number of variant genes completely dominant to their recessive allelomorph, are found to be closely linked in the same linkage groups In the grouse locusts, the linkage was so close as to be equivalent to a single allelomorphic series The occurrence of an outlier of the main group showing only moderate linkage with it was demonstrated by Haldane in the extensive data published by Nabours Nabours has since shown that in one American species of grouse locust (*Acrydium arenosum*) a similar series of pattern factors occurs, showing high frequencies of crossing over

In the course of experiments at the Galton Laboratory, designed to test quite other consequences of natural selection, a brood of *Cepæa nemoralis* has been obtained recently showing apparently 20–25 per cent recombination between the factor for a pink (v yellow), and that for bandless The brood of about sixty young appeared in the summer of 1933, the parents having been taken in Nature about 15 and 28 months previously The pink bandless double heterozygote was evidently in coupling phase, for there survived to be classified in April of this year 17 bandless pink, 18 banded yellow or 35 of the parental combinations, together with 4 banded pink and 5 bandless yellow, making 9 recombinations, evidently due to crossing over

The occurrence of close linkage between a number of genes in natural populations of *Cepæa* has long been recognised[1] though the actual data have not yet been published The unpublished genetic results of A W Stelfox, kindly placed at the disposal of one of us (C D), include a similar back cross between pink bandless and yellow banded, which gave 13 pink bandless and 11 yellow banded, followed by a second generation from bandless pinks of 16 pink bandless and 10 yellow banded Neither of these progenies show recombination, and they are inconsistent with the occurrence of so much as 20 per cent It seems likely that the pinks used in the two sets of experiments were genetically different, and that one is more closely linked with bandless while the other shows appreciable recombination The alternative that the same genes may show variable linkage in different strains is, however, not excluded

Crystalline Œstrus-producing Hormone from Horse (Stallion) Urine

PROF B ZONDEK[1] has published results on the high quantities of oestrus producing hormone present in horse (stallion) urine By application of the method employed in this Institute for the preparation of crystalline oestrogenic hormones from the urine of pregnant mares a few milligrams of crystals of high oestrogenic activity were obtained from 5 litres of horse urine

They were rhomboid plates, melting after recrystallisation from alcohol at 254°-255°, and when mixed with a sample of α folliculin (α oestrone) melting at 257° 259° the melting point of 254°-256° was obtained

As predicted by Zondek by the comparison of the physiological properties, the isolated substance seems to be identical with the hormone of the urine of pregnant women Greater quantities of horse urine are now being worked in order to identify the hormone with certainty

Crocodiles or Alligators?

THERE has recently been published the part of Das Tierreich" dealing with Reptilia Loricata, and since this great work is bound to be widely used by zoologists in the naming of species, it becomes of considerable importance in the stabilising of zoological nomenclature One therefore examines with more than usual interest the generic and specific names adopted by Dr Franz Werner for crocodiles and alligators Again the strict application of the laws of priority in nomenclature gives rise to some confusion The generic name *Crocodilus*, as applied to Old World crocodiles (Crocodilidæ) by Cuvier in 1807, is replaced by *Champse* of Merrem (1820), the reason being that in 1768 Laurenti had used the name *Crocodylus* with another significance

Following Laurenti's usage the name *Crocodylus* is accordingly applied to two South American species of alligators, so that, in the first place, confusion arises between the old-established distinctions between crocodiles and alligators, and, in the second place, the family name Crocodilidæ (although still retained) loses its significance, since it no longer includes the genus *Crocodilus*

More unfortunate still, the specific name of the tropical South American alligator, widely known as *trigonatus*, has following Laurenti, become *Crocodylus niloticus* so obvious a misnomer that its meaning can only lead to confusion

My impression is that the laws of priority provide against the perpetuation of obvious mistakes, in any case if Laurenti more than a century and a half ago, made the blunder of naming a South American form under the impression that he was naming a specimen from the Nile there seems to be no good reason why the blunder should be stabilised in a scientific system It is on a par with, though more confusing than the retention of the name *Certhia familiaris brittanica* for the British tree creeper because Ridgway forgot for a moment how to spell Britain

Sine systemate chaos is the motto printed on the cover of Das Tierreich , but confusion may arise under the cloak of systematics

Air-Pockets in Shore Sands and Winter Packing of the Sea-Bottom

WHILST crossing the Lancaster sands last summer from the village of Flookborough my attention was attracted by a succession of curious sounds all around me, resembling either profound sighs or the strong flat expirations made through pursed lips by a sleeping person These sounds were first heard in daylight, but they may have been heard at night in the past by others and given rise to tales of legendary monsters On searching for the cause I was at once shown it by my companion Mr Thomas Wilson the sounds were due to the escape of air from small pockets below the surface of the wet sand, and could be produced by perforating with one's finger the drying and slightly elevated areas of sand overlying the pockets The vibration produced in the ground by a pedestrian or a passing cockle-cart appears to increase the air pressure sufficiently to blow off the sandy caps of the pockets

It occurred to me that the holes and cavities formed in the sand might be of interest to geologists, since similar ones might have become fossilised in past ages and remain to perplex the palæontologist

These air pockets have been observed near high water mark when crossing the sands soon after the recession of the tide, the following explanation is suggested for their formation At this level the sand dries and drains to a great extent in summer, and especially during the neap tide period When the spring tide floods set in, water flows very rapidly over the area of dry sand, imprisoning air below the wetted surface During high and the following ebb tide water gradually percolates below the surface into the underlying sand, driving the imprisoned air into the looser aggregations of sand where it collects and forms a pocket, which may be blown' by a gradual accumulation of the encircling water pressure or by a sudden increase due to vibration of the ground

These miniature air volcanoes were noticed frequently during the summer, but not during monthly visits in the winter In April this year they have again appeared This apparent periodicity is interesting in connexion with the prevailing view held by British inshore fishermen that the sea bottom on the fishing grounds becomes hard or 'closes up' in winter and loosens or 'opens up' again in the spring: confirmation of this observation—important in quantitative studies on fish and fish food—offers a difficult problem for the biologist The Flookborough sands appear 'harder' in winter, but this may be due to lack of drought and drainage, factors which would not, however, operate below sea level Whether the fisherman's hardening of the sea bottom might be due to biological phenomena, such as a relative quiescence of the in fauna, or to physical causes, remains to be sought

Strange Sounds from Inland Ice, Greenland

DURING the month of August 1932 when setting up the French Expedition of the International Polar Year in Scoresby Sound, on the East Greenland coast, some of my colleagues and I heard four times the mysterious sound called by the late Prof A Wegener the 'Ton der Dove Bai'[1] The sound was heard in the morning, generally at 11 a.m (G.M T), and also during the afternoon It was a powerful and deep musical note coming far from the south, lasting a few seconds It resembled the roaring of a fog horn After that it was not heard during the course of the Polar Year

A Wegener and five of his companions heard it eight times in five different neighbouring places, both during the day and the polar night It lasted some times a few minutes and Wegener ascribed it to the movements of inland ice In fact it seemed, in Scoresby Sound, to come from beyond Cape Brewster, precisely from the part of the coast where the inland ice flows into the sea from the large glaciers

Is this vibrating sound really caused by the detachment of icebergs or is it similar to the desert song', that strange musical note produced by the sand? In fact, there is a close analogy between the fields of powdery dry snow of the inland ice and the fields of sand of the Arabian desert

Spearman's General Factor without the Indeterminate Part

IT is well known that Spearman's two factor theory of intelligence leads to an expression for the general factor g containing an indeterminate part[1] Considerable discussion has taken place on the inconvenience so caused I have proved that if we adhere strictly to the conditions laid down by Spearman, namely, that the general factor and the specific factors are all mutually uncorrelated, we cannot dispense with the indeterminate part[2]

However the problem can be stated in another way, which seems likely to prove much more convenient in practice Let us define the *approximate* general factor g^1 as the determinate part of the formula obtained for g (with a slightly different multiplier so as to keep the standard deviation unity), with a similar definition for the approximate specific factors Then I have proved that these approximate specific factors are all approximately uncorrelated with each other and *exactly* uncorrelated with the approximate general factor For Brown and Stephenson's results no coefficient of correlation of these approximate specific factors is numerically greater than about 0 1

A detailed proof will be offered for publication elsewhere

The Reaction between Oxygen and the Heavier Isotope of Hydrogen

WE have made a preliminary survey of the principal respects in which the reaction of deuterium with oxygen differs from that of ordinary hydrogen The deuterium was prepared by the nearly quantitative decomposition of 97 per cent deuterium oxide by repeated passage over pure iron The reaction with oxygen was studied by methods which have been used in this laboratory in a number of previous investigations of the normal hydrogen–oxygen reaction All experiments with deuterium were made in alternation with blank experiments carried out sometimes with cylinder hydrogen and sometimes with hydrogen made from water in the apparatus used for preparing the deuterium No differences between these different specimens of normal hydrogen were found

The results may be summarised as follows –

(a) With deuterium the chain reaction occurring in the gas phase at 560° and pressures greater than the upper explosion limit has a speed 64 per cent of that shown by hydrogen

(b) For the surface reaction occurring in a packed vessel at 525° the ratio of the rates for deuterium and for hydrogen is approximately 0 65–0 70

(c) The upper explosion limit is higher with deuterium than with hydrogen Our results here correspond to those of Frost and Alyea[1], which appeared during the course of the present work The shifting of the limit is almost exactly what would be predicted from the theory of deactivation by ternary collisions Deuterium, on account of its smaller speed, is a less efficient deactivating agent Using the formulæ given by Grant and Hinshelwood[2] we find that to account for the observed shift of the limit at 550°, 525° and 500° respectively, the values required for the relative collision frequencies of deuterium and hydrogen are 0 67 0 76 and 0 76, the mean being 0 73 The value calculated from the respective molecular weights, assuming equal collision areas, is 0 74 This is, indeed, a good confirmation of the ternary collision hypothesis itself

For the energy of activation of the branching process we find 26,500 calories, which does not differ significantly from the values 25,500 and 26,500 found for hydrogen

From the fact that the effect of the deuterium can be calculated from its speed as above, we must conclude that there is little difference in the actual probability of chain branching with the two isotopes If, as has been suggested[3], the branching depends upon whether at a certain stage of the chain H_2+HO_2 gives $H+H_2O_2$ or $H+2OH$, it will be determined by the breakdown of H–O–O–H into 2OH Then, since no link involving H or D is broken the different zero point energies of the two isotopes will have only a second order effect or none as found In the surface reaction and the steady chain reaction the rates depend not upon simple branching but upon initiation and propagation mechanisms one or other of which must involve the activation or dissociation of H_2 or D_2 The different zero point energies will then give rise to different activation energies and hence to different rates in accordance with observation

It appears therefore that the study of the behaviour of the heavy isotope brings from a somewhat unexpected angle an interesting confirmation of several matters connected with the mechanism of the reaction

Photochemistry and Absorption Spectrum of Acetone

IN a recent letter[1] we noted that the ultra violet absorption band of acetone which earlier workers[2] (with the apparent exception of Herzberg[3]) had regarded as continuous has a fine structure This occurs in the long wave side of the band Bowen and Thomson[4] now record a resolution of the remainder of the band into about four groups each containing about 25 diffuse bands but conclude that the diffuseness of the bands can be attributed to an unresolved close packing of the rotation lines without calling on the additional hypothesis of predissociation In citing the fluorescence of acetone as evidence of the absence of dissociation they make no reference to the fact that it is confined to the longer wave lengths of the absorption band[5] Actually the fluorescence disappears near the wave length at which the line structure noted by us becomes diffuse and while this abrupt change can be readily explained by the onset of dissociation it is not accounted for by the assumption that the diffuse region consists of close packed rotational lines

For the photochemical decomposition of acetone Bowen and Thompson adopt the mechanism which we suggested for the decomposition of aldehydes[6] namely a unimolecular elimination of carbon monoxide according to the equation $R\,CHO \rightarrow RH + CO$ They make no reference however to the different behaviour of methyl ethyl ketone[7] which gives a mixture of ethane propane and butane in comparable quantities instead of only propane This crucial fact is not explained by the hypothesis which they have adopted but is readily understood if the hydrocarbon chains are liberated as free radicals

The photodecomposition of methyl butyl ketone[8]

$$CH_3CH_2CH_2CH_2\,CO\,CH_3 \longrightarrow CH_3CH\;CH_2 + CH_3CO\,CH_3$$

is in complete contrast with that of acetone and was quite unforeseen by us, it would be of interest to know on what grounds these authors are able to regard it as 'not unexpected The initial electronic excitation of the chromophoric group will undoubtedly be associated with various vibrations of the molecule including the deformation vibration mentioned by Bowen and Thompson but in our opinion the energy associated with these vibrations is much too small to account for the decomposition of the butyl chain which in the analogous case of butane requires an activation of 65 k cal'

It may now be suggested that the energy of excitation passes from the chromophoric group to another group within the polyatomic system by a process akin to the radiationless transfer in a collision of the second kind This process which we shall describe as inner sensitisation need not give rise to a quantum yield of unity In a complicated molecule there is likely to be a finite probability that the energy transfer may lead to thermal degradation instead

Chemistry of the Red and Brown Algæ

SOME experiments of ours confirm the results of Dr Russell Wells on the presence of true cellulose in algæ[1] From Laminariæ we obtained cellulose from which we made viscose and which we converted into sugar by the method of Ost This sugar gave phenylglucosazone but no trace of insoluble phenyl hydrazone (indicating mannose) was found

We were led to these experiments by the well known occurrence of mannitol in seaweeds and by the demonstration by Nelson and Cretcher[2] that algin is a polymerised uronic acid Evidently whatever uronic acid occurs in the plant the unit of the cell wall material remains the same

Phosphorescent Beryllium Nitride

ALUMINIUM nitride activated by silicon[1] and boron nitride activated by carbon[2] are the only known phosphorescent nitrides

Phosphorescent beryllium nitride has been obtained by me by passing ammonia gas at 1 000° C for four hours over a mixture of beryllium metal containing ten per cent alumina The product thus obtained shows blue luminescence after exposure to a mercury arc lamp

Research Items

Irradiated Yeast and Rickets. Although a number of questions relating to the action of vitamin D still remain unsettled, the fact that irradiated ergosterol determines the fixation of calcium in the animal organism and hence induces good ossification has been indisputably demonstrated In almost all countries this particular form of prophylaxis is practised by administering definite doses of the irradiated ergosterol dissolved in olive, arachis, sesame, or other oil In discussing this subject before the Royal Lombardy Institute of Science and Letters (*Rendiconti* 66) Prof Ernesto Bertarelli points out that those ergosterol containing oils readily become rancid and have other properties which make them unsuitable as products to be applied extensively as prophylactics He emphasises the advantages of replacing these oily liquids by irradiated dry brewers' yeast, which is rich in ergosterol and easy to take, and remains unchanged over long periods The powdered yeast can easily be mixed with, for example, bread and milk in daily amounts of 0 5–0 75 gm , and the doses are simpler to handle and regulate than are small quantities of oils

Fauna of the Dutch East Indies The latest additions to the faunal studies in the Dutch East Indies ('Résultats Scientifiques du Voyage aux Indes Orientales Néerlandaises de LL AA RR Prince et la Princesse Léopold de Belgique ' *Mem Mus Royal d'Histoire Naturelle de Belgique* Hors Série 1933) are on the Sipunculidæ by J M A ten Broeke and Brachiopoda and Amphineura by E Leloup (vol 2 fasc 3) , on Holothuria by H Engel and Crustacés décapodes d Eau douce" by Jean Roux (vol 3, fasc 13 and 14) and Poissons ' by Louis Giltray (vol 5, fasc 3) Of those the most important is the last, occupying 129 pages and describing a large collection of specimens (850) many of which were caught at the surface by night or found among the corals There are 205 species, 6 of which are new to science A knowledge of the general distribution is much extended most of the species having a very wide range from the Red Sea to Polynesia It is very interesting to note that the fishes of this Indo Pacific zone seldom pass the Hawaiian Islands or Paumotu On the Pacific coasts of Central America one meets with a totally different fish fauna That part of the Pacific between these islands and the American continent seems to constitute an almost complete barrier to colonisation from the west The reason for this appears to be the surface temperature of the sea, as the American coast is bathed by two cold currents, one from the north and one from the south (the north and south equatorial drifts), both taking cold water towards Polynesia the salinity being very much lower than in the Indo Pacific zone and thus a natural barrier is formed for eggs and the young stages of fishes The separation between America and Indo Australia is very ancient, but the Indo Pacific zone has undergone a series of successive continental formations and possesses physical characters suitable for a somewhat homogeneous fauna throughout its whole area, the main centre of dispersal apparently being the Indo Australian archipelago

Gill Movements in the May-fly Nymph An interesting addition to our knowledge of propulsion mechanisms in animals comes from Prof L E S Eastham (*Proc Roy Soc* , B, 115, 30), who has analysed the gill movements in the nymph of the may fly, *Cænis horaria* In this insect the four pairs of gills beat in a normal (longitudinal) direction, but work in such a manner as to produce a current that is transverse The direction is reversible, and no permanent functional asymmetry is involved The gills on one side are found always to be out of phase with those of the other, but, though of some importance this phenomenon proves to be not the only factor concerned in the production of the transverse current Indeed, analysis revealed that several factors were conspiring to that end, involving at least three different mechanical principles The up and down movement of the gill in an elliptical path with the convex side above, and the gill fringe closing on the downward stroke recalls the action of a bird s wing , the change of angle of the gill to the direction of flow brings about what is essentially a screw action while the alternate suction and compression between both successive gills and members of each pair, caused by the metachronal rhythm, has an effect comparable with that of the limb movements in the filter feeding *Cheirocephalus*

A Foliar Endodermis and the Function of the Endodermis Almost throughout the vascular plants, the vascular system of the young absorbing root is enclosed within an endodermis, and the fact that this means that the stelar sap is enclosed within a cylinder of living protoplasts embedded in the peculiar network formed by the Casparian strip has been interpreted as the mechanism determining the osmotic entry of water into the stele Further experimental examination of the passage of solutes across the endodermis has therefore considerable significance, and George Trapp has recently used the foliar endodermis of the Plantaginaceæ, having made a thorough study of its structure and distribution, for a re-examination of its behaviour in retaining solutes Using relatively high concentration of non toxic dyes which were absorbed by cut shoots of *P arborescens*, very definite results could be obtained in comparatively short periods of time Dyes the diffusion of which is confined to the cell membranes were prevented from outward diffusion from the veins wherever the endodermis was present Trapp's experiments are described and discussed, after a discussion of the structure and distribution of the foliar endodermis in this family, in the *Transactions of the Royal Society of Edinburgh*, 57, part 2, No 18, 1933

Preservation of New Potatoes The popularity of the new potato has led to investigations being carried out as to the possibility of devising some method of storage so that the characteristic flavour will be retained Interesting results of experiments on these lines are described by A M Smith in the *Scottish Journal of Agriculture*, 17, 202 Since the thin skin is one of the most highly valued properties of the new potato, immaturity at the time of lifting is essential This is preferably achieved by anticipating the ordinary harvest by about a fortnight, as late planting (the other alternative) is liable to expose the crop to bad climatic conditions Storage of such immature potatoes clearly requires special treatment, as they are more liable to mechanical injury and show a greater respiratory activity than mature tubers. The greatest measure of success was achieved by the following method, attention to conditions of temperature and humidity proving of the first importance. The tubers were packed in ordinary fruit barrels of 2–2½ cu. ft. capacity and stored in a cellar at a temperature of about 40° F. The barrels held 40–50 lb. of potatoes placed in six or seven layers interspersed with a packing mixture of approximately equal volumes of granulated peat and sand, the moisture content averaging between 10 and 12 per cent. The peat helps to retain the moisture while the sand aids aeration. The presence of 1 per cent calcium carbonate appeared to reduce the tendency to sprout in some cases, but both this method and the addition of apples (also claimed as a deterrent to sprout development) need further study before conclusive evidence is obtained. As regards the best variety to use, King Edward appears to fulfil the necessary conditions most nearly, but it is probable that further trial will show that many other varieties are equally suitable.

Grassland and Grazing. An interesting résumé of the experiments on grassland management carried out at Jealott's Hill by Mr. Martin Jones is given in the 1933 issue of the *Journal of the Royal Agricultural Society*, vol. 94. Provided a pasture lies on an adequately drained and limed soil and maintained at a satisfactory level of fertility, the character of the sward can largely be controlled by the grazing methods adopted. In the case of grassland newly sown with a simple mixture of grasses and clover, the latter could be obtained as the dominant if close grazing were carried on from March until May, competition with the earlier growing grasses being thereby avoided. On the other hand, if heavy stocking was always avoided and no grazing at all allowed before mid-April, grasses could be secured as the dominant feature. An intermediate result was brought about by resting the field up to April and then alternating close grazing with intervals of a month's rest. Overstocking in the winter and understocking in the summer induced the poor weedy condition which is of only too common occurrence on farms in general. Similar differential results were obtained with an old established pasture, where equilibrium had apparently been reached for a number of years, the rapid increase in rye grass and clover and the reduction of weeds being specially noticeable. Individual species of grass could also be encouraged at will, the predominance of rye grass or cocksfoot, for example, depending chiefly on the time of year at which the field was rested.

Gemstones. The latest of the series of handbooks on 'The Mineral Industry of the British Empire and Foreign Countries" published by the Imperial Institute is one on "Gemstones" (137 pp. 2*s*. 6*d*.) which summarises in a handy form the economic and statistical information available on this subject. The introduction deals, in a popular style, with the physical characters on which the beauty of the stones depends and mentions the methods used for identifying different species. A description of the various minerals and their modes of occurrence is followed by an account of the methods adopted for cutting and polishing the stones. The main part of the book deals with each producing country, describing the stones obtained, the location, type and extent of the deposits and the method of working. Technical data for the expert and interesting information for the gem lover are also provided. A useful list gives the London prices for cut gemstones of various qualities and weights. About five sixths of the world's annual output of diamonds is produced in the British Empire, which is also well furnished with supplies of other important stones. Australia contributes opal; India, Burma and Ceylon provide jade, sapphire, ruby, spinel, agate, garnet, tourmaline, chrysoberyl, zircon, moonstone and the various forms of quartz; South West Africa yields tourmaline and beryl and South Africa has deposits of beryl and emerald. The volume should be read by all interested in gemstones and in the gem industry.

Saxton's Maps of England and Wales. The county maps of England and Wales by Christopher Saxton published between 1574 and 1579 provided material for English maps for a long period, but very little is known of the method Saxton used in compiling his sheets. In many of the sheets there are certainly striking omissions of physical features large enough to be shown on the scale used. Mr. G. Manley has studied the problem in certain of the Pennine sheets and makes some interesting suggestions in a paper in the *Geographical Journal* of April ('Saxton's Survey of Northern England'). Mr. Manley finds that Saxton's choice of hills to be marked was dictated by several reasons: historic names, sources of streams, beacon hills, boundary hills and lastly a category of hills that are characterised if anything by the extent of the view which they offered from the summit but not necessarily by great height. These would appear to be hills which Saxton or his assistant climbed. He may have gone up other hills but it is unlikely. Certainly his river valleys are often incomplete at their heads. From the hill tops he reached, Saxton seems to have estimated distances along single bearings. He was careful about detail in well inhabited lands, but worked rapidly in uninhabited country, where his maps are weakest, especially when he surveyed by this method a rugged land like the northern Pennines and Lake District, where much detail at lower altitudes was hidden from his elevated viewpoints.

A New Objective for X-Ray Cinematography. A new objective specially computed for X-ray cinematography has been produced by Messrs. Carl Zeiss and is described in the *Zeiss Nachrichten* of April 1934. This lens has several unusual features which are of interest. For the cinematography of the fluorescent screens used in X-ray work a very fast lens is required on account of the small amount of light available. The new lens, the *R* Biotar, has an aperture of *f*/0.85, which is larger than that of any satisfactorily corrected lens previously available. In computing it, special attention has been given to the reduction of spherical aberration, which judging by the details given has been very successfully done. The lens has, however, no depth of focus, and a very narrow field, neither of which defects is important for the purpose for which the lens is to be used. With such a large aperture the dependence of the correction on object distance is very large, so that in its normal form the lens can only be used when the distance of the object is large compared with the focal length A special lens has been designed for use in sound film work where closer objects are used On account of its unusual proportions, the lens, which is made for both standard and substandard cinematography, can only be used in existing cameras after alterations have been made to the latter Moreover, no iris diaphragm is provided as this would still further increase the difficulty of using it in existing cameras With such critical focusing as is required, it is necessary to ensure that the film lies perfectly flat and that successive frames come into exactly the same place The light emitted from the fluorescent screens used lies almost entirely within the visible region, and the transmission of the lens in this region is very good although 30 per cent of the incident light is lost by reflection at the glass air surfaces This lens in combination with modern high speed photographic emulsions makes possible X ray cinematography at a picture frequency approaching that normally used

Trichromatic Reproduction in Television In a paper read before the Royal Society of Arts on May 2, Mr J C Wilson gave an account of some experiments that have been conducted in the Baird television laboratories in an attempt to develop a television system in which the transmitted scene is reproduced at the receiver in colours The scanning at the transmitter and receiver was accomplished by the use of a scanning disc with three spiral segments, each segment containing 15 holes The three segments were responsible for the red green and blue components of the picture respectively, and by rotating the disc at 600 r p m the image was scanned 30 times per second in all, 10 times per second in each colour The system is thus a trichromatic system in which the three colours are presented successively and fused owing to the persistence of vision, only one channel between transmitter and receiver is therefore required The holes in the scanning disc were covered with the appropriate coloured gelatine filters, and the photoelectric cells at the transmitter were selected to give a satisfactory balance between the three sets of signals The light sources at the receiver comprised a neon lamp and a mercury vapour lamp While the colour quality of the reproduced image was apparently quite good, the definition with only 15 lines was very crude and any extension of the method is limited by the limitations inherent in mechanical scanning devices The work was, however, mainly intended to investigate the nature of the problem and the difficulties that have to be overcome

Removal of Sulphur Dioxide from Library Air It is well known that books and papers stored in cities where atmospheric pollution is high are in a uniformly poorer state of preservation than similar books and papers stored in country or suburban localities where the air is purer Experiments have shown that papers exposed to an atmosphere containing sulphur dioxide in an amount varying from 2 to 9 parts of sulphur dioxide per million parts of air for 10 days underwent pronounced physical and chemical deterioration, manifested by a large increase both in brittleness and acidity A valuable study of a method of removing sulphur dioxide from the air entering a library has recently been published by the Bureau of Standards, Washington (Misc Publications, No 142 5 cents) Tests were made in the Folger Shakespeare Library, Washington They show that the sulphur dioxide is not completely removed from the air by washing it with untreated water in an air conditioning system Effective elimination was obtained on washing the air with water that had been treated with alkaline material at a rate sufficient to maintain the hydrogen ion concentration of the wash water within the range 8 5 to 9 It was proved that the sulphur dioxide content of the washed air was entirely dependent upon the hydrogen ion concentration of the wash water The composition of a specific mixture of chemicals commercially available was found to be very satisfactory An air washer of the commercial type using untreated water does not remove enough of the sulphur dioxide from library air The hydrogen ion concentration should not be allowed to rise above *p*H 9 0 owing to the danger of removing zinc from brass fittings

Nessler's Reagent. An alkaline solution of mercuric iodide and potassium iodide, probably containing the compound HgI_2, 2KI, is Nessler's reagent and gives a brown colour or precipitate with ammonia The composition of the brown compound has been variously given since its discovery by Nessler in 1856 but in a recent study (Nichols and Willits, *J Amer Chem Soc*, April 1934) it is shown to have the composition represented by the empirical formula $NH_2Hg_2I_3$ The compound is very insoluble and tends to form in very minute particles, which are negatively charged and form a colloidal solution These particles can be separated by ultra filtration They are formed instantaneously in the reaction When ammonia solutions of higher concentrations are nesslerised, the yellow colour changes to red owing to agglomeration of the particles This may be prevented and the colour made permanent over a wider range of concentration of ammonia by adding a protective colloid, for example, by adding to 50 ml of Nessler solution 1 ml of a 0 5 per cent alkaline ash free gelatin solution containing 1 per cent of perhydrol The colour is of as great or a greater intensity than that produced in the standard method

Stellar Spectra of Type *B* A detailed study of the wave lengths, origins and behaviour of lines in *B* type spectra was made in 1931 by Dr Struve (noted in NATURE, 129, 442, 1932) Much work still remains to be done on these lines, and an important contribution has now been made by R K Marshall (*Pub Obs Univ Michigan*, 5, No 12) The spectra of 11 stars (the same as those discussed by Struve, with one exception) were measured over the range 3587 5047 A, with special attention to the near ultra violet They were all taken with the single prism spectrograph of the 37½ in Ann Arbor reflector Intensities of all measurable lines are given as found in each of the 11 stars (which range in spectral type from *O*9 to *B*8), together with the atomic symbol, when identified, and the laboratory wave lengths and intensities Of the 534 lines finally tabulated as genuine, only half have been even provisionally identified, and only about two fifths of these are considered as satisfactory identifications An interesting set of spectrophotometer tracings shows the differences between individual spectra as well as the main general features, and the variations of intensity with spectral type of the more important lines are also well marked

The Hawke's Bay Earthquake of February 3, 1931

THOUGH not in the front rank among the seismic regions of the world, New Zealand has been visited by several earthquakes with great crustal changes, such as those of 1823, 1848, 1855 and 1929 All these occurred in sparsely inhabited regions, and the death roll of New Zealand earthquakes has hitherto been small, the greatest loss of life before 1931 being that of 17 persons during the Murchison or Buller earthquake of 1929 For the first time in its history, New Zealand, on February 3, 1931, experienced an earthquake in the neighbourhood of important towns, the population of Napier being 16,025, and that of Hastings 10,850

The official report on the earthquake has recently been issued* It is the joint work of several writers The general account of the earthquake is given by Mr F R Callaghan, its geological aspects are described by Mr J Henderson, the director of the New Zealand Geological Survey, and the seismological phenomena by Dr C E Adams Mr M A F Barnett and Mr R C Hayes Mr P Marshall studies the effects of the earthquake on the coast line near Napier, and Mr S W S Strong the uplift in Sponge Bay In the concluding section, Messrs A Brodie and A G Harris report on the damage to buildings The whole volume is a notable contribution to our knowledge of an interesting earthquake

The east coast of the North Island, from Cape Palliser to East Cape, a distance of about 300 miles, is practically straight, except for the deep indentation of Hawke's Bay, 50 miles across Napier lies on the south west coast of the bay, Hastings about 12 miles to the south

The first known earthquake in the district since its settlement seventy five years ago occurred on February 23, 1863 Several houses in Napier were then destroyed On May 7, 1890, and again on August 9, 1904, the district was severely shaken by earthquakes with centres 180–200 miles south east of Napier On July 21 1921, there was a strong local earthquake with its centre about twenty miles inland During the next ten years, a number of slight or moderate shocks occurred either along an inland band or some distance out to sea, but the epicentral region of 1931 remained inactive

Suddenly, without any warning shocks, the great earthquake began at 10 17 a m on February 3 (February 2, 10 47 p m, G M T) The shock was in two parts The first part became rapidly stronger and was an uplifting movement combined with violent and confused swaying Then, after a pause of about 30 seconds, followed the second part with a motion resembling a sharp bump downwards The total duration was timed as 2½ minutes The number of known deaths was 256—161 in Napier, 93 in Hastings and 2 in Wairoa

The isoseismal lines, depending on the Rossi Forel scale of intensity, are reproduced in Fig 1 They show that the intensity decreased rather regularly with increasing distance from the epicentre, except towards the south west In this direction, the disturbed area reached so far as Timaru, 460 miles from the epicentre, while the shock was not felt at Auckland, only 200 miles to the north west The area of destruction, bounded by the isoseismal 9, is elongated, being about 100 miles long and 30 miles wide Within it is a smaller area of similar form, in which the intensity reached the highest degree, 10, of the scale

From the seismographic records at three stations (Arapuni, Wellington and Takaba), it was ascertained that the epicentre lay in lat 39° 20′ S, long 177° 0′ E This point, represented by the black spot in Fig 2, lies close to the west coast line of Hawke's Bay, about 12 miles north of Napier The same records give a focal depth of about 13 miles, which is approximately the same as that of several of the stronger after shocks

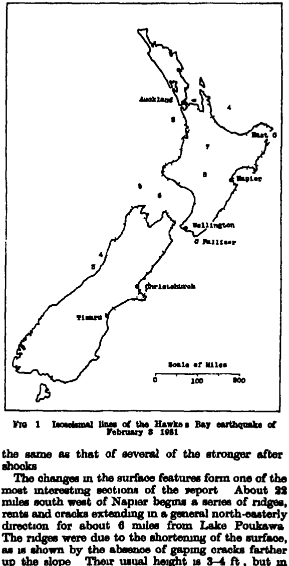

FIG 1 Isoseismal lines of the Hawke's Bay earthquake of February 3 1931

The changes in the surface features form one of the most interesting sections of the report About 22 miles south west of Napier begins a series of ridges, rents and cracks extending in a general north-easterly direction for about 6 miles from Lake Poukawa The ridges were due to the shortening of the surface, as is shown by the absence of gaping cracks farther up the slope Their usual height is 3–4 ft, but in places they rise 6–8 ft above the general surface They indicate that, as a rule, the country on the west side of the ridges moved relatively eastwards, and by an amount that, judging from the effect on the wire fences, must be measured in feet rather than in inches At one point, indeed, a road is displaced horizontally between 6 ft and 7 ft Still farther to the north are two other similar series of ridges The persistence of these ridges, along courses several miles in length, clearly points to movements along deep seated fractures

* N Z, Department of Scientific and Industrial Research, Bulletin No 43 Report on the Hawke's Bay Earthquake (3rd February 1931) Pp. 116 (Wellington, N.Z Government Printer, 1933) 5s

After the earthquake, the uplift of the land was at once noticed at Napier and along the coast to the north Inland, however, it could only be traced by the rise of the bench marks Three lines of levelling were carried across the low lying plain to the south of Napier They revealed the existence of a line or narrow zone of no change, running south west from a point on the coast about a mile south of Napier, and parallel to the ridges near Poukawa, etc , described above The country north west of this neutral line was elevated as a whole, and that to the south east of it depressed, the greatest amounts shown on the sections being about 5 ft upwards and nearly 3 ft downwards The first series of levels was made between June and October 1931 In March and April 1932, the levellings were repeated, and these showed that, in the interval, the upraised mass had sunk as a whole and fairly regularly, the subsidence being most marked (a little more than a foot) at points where the previous uplift was greatest The re triangulation of the district revealed displacements of three points by 13 in , 13 in and 49 in

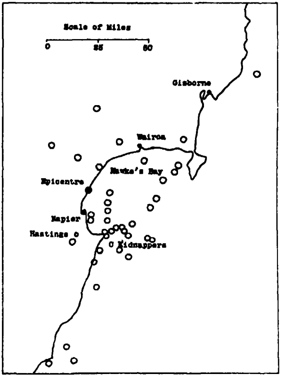

Fig 2. Hawke s Bay region Circles indicate epicentres of after-shocks of the earthquake of February 3 1931

The disturbances of the beach first become notable at a point 7 miles south of Napier At the north east corner of the Scinde Peninsula, on which Napier stands, the tide-gauge indicated a rise of 6 ft Between this point and the entrance to Port Ahuriri, to the west of the city, the uplift was manifest from the bleached remains of calcareous Algæ The Ahuriri Lagoon is shallow and its floor flat The outer margin was raised 6 ft. and the inner 3 ft 9 in As a result of this movement, wide areas of the lagoon floor have been laid bare at all states of the tide The total area of new land is estimated at about 5 sq miles Farther north, the uplift gradually increased from about 6 ft 6 in at a point 10 miles north of Napier to 9 ft at one 10 miles beyond Two miles to the north of the latter point, however, it seemed, though obscured, to decrease rapidly, until at and beyond a point 24 miles north of Napier, the uplift was too small to be discerned, with the exception of a small area to the west of the Wairoa River, in which there was a rise of about 2 ft

The floor of Hawke's Bay is regular, the depth of water increasing slowly outwards to about 8 fathoms at a distance of one mile After the earthquake soundings were made in the bay These showed a rise of about 6 ft , as on the adjoining coast Later in February, and again a year afterwards, further lines of soundings were carried out, but, beyond the reduction in depth by about 6 ft , it was clear that there had been no marked distortion of the sea bed

Assuming that the fracture traced on land crosses the floor of Hawke's Bay to the uplifted coast beyond it follows that the total length of the dislocation is not less than 40 miles a length comparable with that of the fissures formed with the earthquakes of 1848 and 1855 Mr Henderson thus concludes that, at the time of the earthquake an earth block, about 60 miles long in a north east direction and at least 10 miles wide at one place, was uplifted and that its central portion—and probably the whole block—was tilted gently and uniformly to the north west

One more phenomenon—and it is a most unusual one—may be noticed On February 17, or a fortnight after the earthquake some men were working on the beach of Tuamotu Island near Gisborne, when they witnessed the rapid uplift of a bank formerly covered by a foot or two at low water, to an average height of 7 ft They state that the reef ' just rose out of the sea without warning' The new reef is in Sponge Bay, 2½ miles from Gisborne, and has an area of about 2 acres Its surface is slightly dome shaped and is covered with large boulders At the same time, the adjoining land was depressed a few feet and broken into segments by numerous fissures No earthquake was felt with the movement, nor was any recorded in the adjoining district

The after shocks were registered at Wellington Hastings and elsewhere At the former station, 175 miles from the epicentre the numbers of shocks recorded were 151 on February 3, and, on successive days, 55 50, 29 24 21 12, and so on, until February 13, when there was a renewal of activity with 81 shocks, including one severe earthquake of intensity 8, with its epicentre 34 miles east of Napier From February 3 until March 3, the total number recorded was 612 During February, 590 shocks were registered at Hastings, the total number until the end of the year being 938 The epicentres of 40 after shocks from February 3 until the end of June 1932 were determined from the records These are indicated by the small circles in Fig 2 It will be seen that most of the after shocks originated beneath Hawke's Bay, especially in its southern portion Many of them are grouped along two bands, one running north from Cape Kidnappers, and the other in the east north-east direction from the same cape for 10–15 miles, and then striking north east right across the mouth of the bay C Davison

Exhibition of Technical and Scientific Chemical Apparatus at Cologne

THE Seventh Achema (Exhibition of Technical and Scientific Chemical Apparatus) was duly held at Cologne in the spacious and centrally situated permanent exhibition buildings on May 18–27. It is a testimony both to the importance of the exhibition itself and to the newer national development of the chemical industry in all countries that it was very largely visited by foreigners. More than 2,000 were expected, including a considerable and influential party of British chemical and chemical plant manufacturers, who spent several days in studying it and who are reported individually to have found the time well spent.

With past traditions to encourage her, Germany is striving to retain the lead which she formerly gained in this field, and although there was nothing particularly outstanding or novel on display, there was much among the exhibits of the three hundred firms to interest the serious. The method of display of the exhibits on small open stands of uniform character has much to commend it, and was thought by many to be preferable to the closed stands adopted at the British Industries Fair. Needless to say, the representatives at the stands were well versed in the technicalities of their wares and able usually to deal with technical points raised by the visitor, who frequently also found a willingness to discuss the special problems he brought forward at further private meetings or at the exhibitors' own works. The problems of the industry are so variable that standard apparatus has frequently to be modified to meet the particular requirements, and the Germans are known to be particularly adaptable in this respect.

The exhibits covered a wide field and were perhaps the more valuable in consequence, whereas the last exhibition of British chemical plant held in London, at the time of the jubilee of the Society of Chemical Industry, was restricted almost entirely to plant. Such collective displays as those made by the publishers of the many technical and scientific books were a feature that should be copied, as also the exhibit covering safety regulations and precautions in the industry. It is proper that chemists should be as meticulous in the treatment of the health and safety of their work people as they are of their reactions, and indeed it is well known that the industry is one of the safest in spite of the potentialities for danger in it.

The tendency, if there were one, was towards the exhibit of apparatus for copying large scale working in the laboratory. The development of chemical processes at high pressures and elevated temperatures had its influence on the apparatus exhibited, whilst the ceramic section, which was a particularly good one, illustrated the progress which has been made in using substances which corrode metals or require high temperatures to react.

As compared with the last exhibition, there was less display of large scale processes requiring a good deal of space and plant for the exhibit, more attention being paid to details. The urge to break away from tradition was sometimes in evidence as, for example, in the vest pocket microscopes.

The spacious gangways made it physically possible to spend some hours at a time at the somewhat arduous task of examination, and the important social side was facilitated by a club room for overseas visitors and other concomitants associated with the Rhine.

Dr. Bretschneider, the organiser of the exhibition, was in evidence on all occasions as a willing and charming helper to all visitors, and all felt how much they owed to his indefatigable energy in organising such a treasure house of chemical weapons. The British visitors found the Rhineland and the Moselle as simple, clean and convivial as ever, whilst travelling was in no way fettered by restrictions of currency or otherwise—they received a real welcome from all. It is well to record that at no time did they see any evidence which would lead them to believe that other than a peaceful reconstruction of Germany is taking place.

Annual Conference of the Association of Teachers in Technical Institutions

AT the recent (twenty-fifth) annual Conference of the Association of Teachers in Technical Institutions, held at Middlesbrough, Mr. H. J. Cull, of the Central Technical College, Birmingham, took over the presidency of the Association from Mr. F. H. Reid, of the Technical Institute, Paddington.

Mr. Cull opened his presidential address with a survey of the results of the application of science to industrial processes, and stressed specially the growth of 'technological unemployment'. "These are the days," he said, "of the second industrial revolution—the coming into full use of electricity and the internal combustion engine. The difficulties are greater than those which marked the passage into full use of steam power, mainly on account of the speed of the development." He instanced the following as illustrations of his point: the rise in production of several nations between 1925 and 1929 was 38 per cent in Poland, 54 per cent in Canada, 30 per cent in France, 22 per cent in Germany, 14 per cent in the United States and 13 per cent in Great Britain. More important, perhaps, was the physical output per worker: in Great Britain in 1924–29 there was an increase of 11 per cent. The figure for the United States rose by 50 per cent in a quarter of a century. In 35 typical American factories the output per man hour between 1919 and 1927 rose 74 per cent. "It is futile," said Mr. Cull, "to think of retarding these scientific applications, and of 'scientific holidays', and so the consequences remain to be faced … it is now apparent that this machine age will demand that, if employment is to be continuous, skill will be judged by adaptability. It is for future consideration to show the precise form of the demands of this changing industrial condition on the technical teacher." Mr. Cull then linked with his general picture of these industrial changes their implications of the work of junior technical schools, juvenile instruction centres, continuation classes, regional co-ordination of technical education, etc., and the need for educational research. He also directed special attention to the course for laboratory assistants promoted by the

Institute of Physics in order to remove from some of these appointments the suggestion of blind alley employment

At the Association's annual dinner, the question of industrial changes and the need for adaptability was deftly sketched by Dr R E Slade (Imperial Chemical Industries, Ltd) who responded to the toast of 'Education and Industry" Since world markets are changing he said, industry must keep pace with the changes On the north east coast, industry has one of the finest positions in a free trade world, but since the free trade world no longer exists, industry is compelled to adjust itself At the Imperial Chemical Industries works at Billingham they set out to send nitrogenous fertilisers all over the world The plant was completed in 1929 But the world now requires only a portion of these fertilisers, and the firm had to turn its attention to other products for home and export purposes The factory is now working hard on other things, and is being extended Dr Slade insisted that changes in industry can be achieved only by full confidence in technical and research staffs Only the association of commercial minds with scientific and technical possibilities will lead to success Workers on Tees side he declared, are wonderfully adaptable, and this is due to technical training

A resolution passed during the Conference urged the necessity of grace periods up to one year in order that technical teachers could undertake research or gain further industrial experience Other resolutions pressed for an extension of part time day classes which would be attended by students during the normal working hours of industry, and for closer co operation between the Board of Education and the Ministry of Labour in connexion with juvenile instruction centres

University and Educational Intelligence

CAMBRIDGE —Dr O M B Bulman, of Sidney Sussex College has been appointed University lecturer in geology M Black, of Trinity College, has been appointed University demonstrator in geology Dr G N Myers of Sidney Sussex College University demonstrator in pharmacology and Dr H A Krebs University demonstrator in biochemistry

An election to the Isaac Newton studentships will be held early in the Michaelmas Term 1934 These studentships are for the furtherance of advanced study and research in astronomy (especially gravitational astronomy) and physical optics Candidates are invited to send in their applications to the Vice Chancellor between October 9 and October 15

LIVERPOOL —Dr Henry Cohen, lecturer in medicine in the University and honorary physician to Liverpool Royal Infirmary, has been appointed to the chair of medicine in the University in succession to Prof John Hay, who retires at the end of the present session

---

PROF L M MILNE THOMSON, assistant professor of mathematics at the Royal Naval College, Greenwich, has been appointed professor as from September 30 next

AN International University Conference has been arranged by the Association of University Teachers to be held at Oxford on June 29–July 2 This Conference will be the first attempt to form an organ of direct co-operation between universities of all countries Among the subjects to be discussed at the Conference are university organisation, vocational instruction, interchange of teachers, opportunities for research by foreign students, academic freedom Further information can be obtained from Prof R C McLean, University College, Cardiff

THE first Register of the London School of Economics and Political Science (Houghton Street, Aldwych 3*s* 6*d*) which has just been published contains, in addition to short biographies of former students and a list of lecturers since 1895, an interesting introduction contributed by Sir William Beveridge, the director of the School, describing its growth At first the School did not prepare students specifically for examinations In 1895 there was no teaching University of London, no internal degree, no university professoriate and no faculty of economics There was an examination authority and there were individual colleges such as University, King's or Bedford, but these had no organic relation to each other or to the examining authority The teaching University as it has grown since 1900 out of the London colleges is a new thing altogether Since the War, there has been a rapid growth in the number of regular students of normal university type attending the School, and this has been accompanied by a decline in those listed as occasional The number of regular students is now about 1,300 that of occasional students about 1,100, while the regular teaching staff numbers 89

THE report of the president of Columbia University, New York, Dr Nicholas Murray Butler, for 1933 includes a discussion of some fundamental questions relating to the organisation and development of universities in the United States Dr Butler admits the confusion which results from the lack of an official definition of a university in the United States and of authority for its creation and recognition Nothing is easier than for a college in this country to call itself a university, even though it has not the first characteristic of university organisation, method or ideal" There is no such thing as a private university, he says Some may be supported by taxes and others not, but all are public institutions The American college covers the field which on the Continent is occupied by the upper years of the *lycée* or *gymnasium* and the first year of the university Hence there are but 11 universities in England, 4 in Scotland, 1 in Wales, 5 in Belgium and 8 in Holland, 17 in France and 23 in Germany, 3 in Austria 4 in Hungary 25 in Italy and 11 in Spain But in the United States there are 263 universities, colleges and technological institutions approved by the Association of American Universities Of these, 36 are institutions having a more or less complete university organisation The *World Almanac* lists 579 universities and colleges in the United States The tendency in the United States appears to be to regard the graduate student only as doing 'university' work "The university student", says Dr Butler, has a quite different outlook and a quite different method of approach to his field of intellectual interest " The teaching staff at Columbia in 1932–33 was 3,064 (comparing with 3,255 for the previous session) and 5,609 degrees, certificates and diplomas were granted, the total number of resident students being 30,583, of whom 13,144 were graduate and professional students

Science News a Century Ago

Entomological Society: Prizes for Essays

At a general meeting of the Entomological Society, held on June 2, 1834, the Rev William Kirby, F R S , honorary president, in the chair, a scheme for the establishment of prize essays to be awarded by the Council, on the subject of noxious insects and remedies was adopted, one of the principal objects of the Society being to make its labours practically useful Accordingly, an annual sum of five guineas, or a gold medal of the like value, would be made available for the writer of the best essay (drawn up from personal observation) upon the natural history, economy, and proceedings of such species of insects as are obnoxious to agricultural productions, to be illustrated by figures of the insects in their different states , together with the result of actual experiments made for the prevention of their attacks or the destruction of the insects themselves It was decided that the subject of the essay for the year 1835 should be the turnip fly (Entomol Soc *Journal of Proceedings* 1834)

Public Education in Great Britain

Early in 1834 Parliament had granted £40,000 for assisting the National Society for Educating the Poor and the British and Foreign School Society in erecting schools, this being the first grant of its kind On June 3, 1834, Mr J A Roebuck M P for Bath, moved for the appointment of a select committee to inquire into the means of establishing a system of education Nobody he said, would contest that the legislature considered the moral and intellectual improvement of the people so important as to justify an inquiry, in order to ascertain how far their moral and mental culture could be affected, influenced, or promoted by the Government The motion was seconded by Sir W Molesworth who considered that the education of the lower classes was as deficient in quantity as it was in its quality, and it left the minds of the people in a state of indifference which could not but be condemned by every well thinking individual Lord Morpeth supported the motion, remarking that the grants already made could only be looked upon as experimental, as they were quite inadequate for the purpose of general education After considerable discussion on the suggestion of Lord Althorp Chancellor of the Exchequer, the motion was altered to read that a select committee be appointed to inquire into the state of education of the people of England and Wales and into the application and effect of the grant made last session for the erection of school houses and to consider the expediency of further grants in aid of education"

The Royal Society

On June 5, 1834, ten additional candidates were elected into the fellowship, following nineteen elected previously in April Their names were John, Marquess of Breadalbane, Charles John, Lord Teignmouth, the Hon George Elliot, the Rev Frederick William Hope, Joseph Jekyll, the Rev Robert Murphy, Sir George Rose, Richard Twining, William Robert Whatton, Dr George Witt

Among the newly elected in the above list, only a few can be said to have achieved distinction in science, social and family connexions in the main seeming to serve as claims to recognition The Rev F W Hope, entomologist, is held in universal esteem for his contributions to entomology, and as founder of the chair of zoology in the University of Oxford Hope took an active part in the formation of the Zoological Society in 1826, and of the Entomological Society in 1833 Robert Murphy, mathematician, was one of the seven children of a shoemaker He early evinced mathematical qualities of mind and ultimately graduated at Cambridge as third wrangler William R Whatton, surgeon and antiquary, was not long a fellow He died on December 5, 1835, in his forty sixth year

Steam to India

In the *Mechanics Magazine* of June 7, 1834, it was stated that The House of Commons has on the motion of Mr Chas Grant appointed a select committee to inquire into the best means of promoting steam communication with India The Messrs Seaward of the Canal Works, Millwall in a pamphlet which they have recently published on the subject, recommend that vessels of very large capacity should be employed—of 1,600 tons, for example, with engines of 246 horse power Such a vessel, they say, would allow of 900 tons being appropriated to merchandise, 100 to provisions and water and 460 to coals—which last would suffice with occasional assistance from the wind to carry her to the Cape, where a further supply of coal could be obtained The time occupied on the voyage is calculated not to exceed eleven weeks In 1825, the steam vessel *Enterprise* had made the voyage from Falmouth to Calcutta via the Cape, but she had taken nearly four months for the passage Five years later, the Admiralty started a steam packet service from Falmouth to various Mediterranean ports, and through this came the proposal to send mails by sea to Alexandria, whence they would be taken overland to Suez where a steam vessel would be waiting to convey them to Bombay By an agreement between the British Government and the East India Co , this scheme came into force in 1837, thus reducing the time for letters to reach India by a half

Wellington as Chancellor of the University of Oxford

On Monday, June 9 1834, the Duke of Wellington arrived at Oxford for his installation as Chancellor of the University, alighting at the gate of University College of which the vice chancellor was the master His election had been received with much enthusiasm, and the proceedings of June 10–13 were marked by many brilliant gatherings On Tuesday forenoon, he proceeded to the Theatre accompanied by Lords Londonderry Montague, Apsley and Hill, and on opening the Convocation declared that it had been convened for the purpose of conferring the degree of doctor of civil law on several distinguished individuals including the Dutch Minister, the late Russian Minister, the Dukes of Buccleugh and Newcastle, the Marquises of Salisbury and Bute, the Earls of Warwick and Winchelsea and others Next morning, another gathering took place in the Theatre, of which the galleries, as before, were crowded with undergraduates who cheered the names of Wellington, Nelson, Canning and Pitt and the mention of the House of Lords and the University of Oxford, but showed their disapproval of references to the University of London, the "Gower Street Company" and the admission of Dissenters

Societies and Academies

LONDON

Mineralogical Society, March 15 ARTHUR RUSSELL Baryte crystals from the Manvers Main Colliery, Wath upon Dearne, near Rotherham, Yorkshire A cavity containing exceedingly beautiful colourless crystals of baryte was discovered in the roof of the Parkgate Seam of this colliery in 1930, and the occurrence was briefly described by C P Finn in the same year Two distinct habits of crystals occurred, prismatic and tabular The crystals are attached to cream coloured rhombohedra of dolomite which form a coating on the grey sandstone, both baryte and dolomite being for the most part more or less thickly sprinkled with small bright twinned crystals of chalcopyrite The crystal forms present are listed and drawings of the crystals are given W Q KENNEDY The conditions for the crystallisation of hornblende in igneous rocks By means of a statistical study of the MgO CaO FeO ratios of igneous hornblendes it is shown that the latter occupy an intermediate position between the diopsidic pyroxenes and the magnesia rich, lime poor monoclinic and orthorhombic pyroxenes It is concluded therefore, that (1) pressure and the concentration of the volatile constituents are not the sole determining factors in the crystallisation of pyroxene and hornblende from a magma, but that the original proportions of the constituent oxides play an equally important part, (2) a magma which will produce hornblende as its ferromagnesian constituent under physical conditions tending towards the retention of the volatile constituents will, under effusive conditions, produce diopsidic pyroxene + hypersthene or enstatite augite (pigeonite) ARTHUR RUSSELL An account of British mineral collectors and dealers in the seventeenth, eighteenth and nineteenth centuries (contd) John Williams of Scorrier House, Cornwall, mine agent and adventurer, copper and tin smelter and banker, born September 23, 1753, died April 17, 1841 The collection of Cornish minerals which he had formed at Scorrier in conjunction with his son John (born August 3, 1777, died August 11, 1849) was greatly added to by the latter The collection, which contained about 10 000 specimens, was one of the three finest in Cornwall In 1893 Mr John Charles Williams disposed of the collection by presentation between the British Museum, the Royal Institution of Cornwall, Truro Museum and the Robert Hunt Memorial Museum, Redruth In addition to a memoir of both the Williams, a general account of the collection and its outstanding specimens is given M H HEY (1) On the advantages of the face adjustment for two circle goniometry The statement often made that an accurate projection cannot be so quickly prepared from two circle measurements made with the face adjustment as from measurements made with the zone adjustment is shown to be incorrect, and a construction for the preparation of a projection is described The face adjustment has several decided advantages over the zone adjustment (2) An improved method of crystallographic computations A system for the computation of the elements of a crystal from two circle goniometric measurements is described in which due weight is given to each measured angle in accordance with its estimated probable accuracy (3) On face- and zone symbols referred to hexagonal axes a correction The system of four index hexagonal zone-symbols described by L Weber is correct, and that formerly described by the author is abandoned The derivation of Weber's symbols from a gnomonic or linear projection is described, and their relation to the three index' symbols noted

Physical Society, April 20 LORD RAYLEIGH Further experiments in illustration of the green flash at sunset An artificial source of light and a prism, the dispersion of which is equal to the atmospheric dispersion, was used A straight edge parallel to the base of the prism plays the part of the horizon The observer was 74 metres from the prism On moving the eye into the shadow of the straight edge the bluish green flash was well seen By means of substantially the same arrangement with large dispersion and short distances, the simultaneous contrast effect of a red or orange background was studied, but it was not found possible to obtain a green as opposed to a blue flash in this way With a liquid containing small particles in suitable concentration in front of the source, the disappearing flash is of a brilliant green colour It is concluded that when the flash is bright green, atmospheric filtration is acting to remove the blue light D H FOLLETT An ultra violet photoelectric spectrophotometer The transmission of the sample is found by comparison with a rotating sector of cylindrical type Two photocells are employed and fluctuations in the intensity of the source are compensated for A S RAO and S GOPALAKRISHNAMURTY The spectrum of trebly ionised bromine Vacuum spark and discharge tube spectra of bromine have been investigated over a wide range Many of the triplets and singlets involving the terms due to *4p*, *5s*, *4d*, sp^3 and *5p* configurations have been identified From the present work the classifications made by S C Deb appear to be incorrect The deepest term $4p^3P_0 = 404{,}892$ cm^{-1} yields an ionisation potential of about 50 v for the trebly ionised atom of bromine T C SUTTON and H L HARDEN The purity required for surface tension measurements The extent to which impurities affect the measured value of the surface tension of a liquid depends on the method of measurement employed This effect is applied to test whether the purity of a sample is adequate for the measurement of the surface tension of the pure liquid E E WRIGHT Velocity modulation in television The motion of a spot of light of constant intensity, necessary to produce the effect of a sinusoidal linear distribution of light intensity on a television viewing screen, is determined and the effect of the finite size of the scanning spot is compared with the analogous effect in the more usual type of television system in which the scanning spot moves with constant speed and is modulated in intensity

Society of Public Analysts, May 2 A SHAW Determination of free silica in coal measure rocks Whilst the method of rational analyses for the determination of free silica in coal measure rock tends to give results too low by about 2 per cent, it is far more accurate than calculations from the ultimate analysis, micrometric measurements of shale sections, or X ray analysis S A ASHMORE A new apparatus for determining the temperature of crystallisation of cocoa butter The temperature at which separation of solid fat occurs is a constant for each fat, and an apparatus has been devised whereby this temperature can be determined with rapidity and precision on as little as 2 gm of fat The Tyndall effect has been utilised by projecting a beam of light through a small tube containing the melted fat suitably enclosed in a darkened chamber, as soon as any separation of solid particles occurs, a scattering of light takes place, and the tube appears luminous against the darkened background S A Coase Determination of small quantities of germanium in the presence of arsenic The electrolytic reduction of germanium dioxide to monogermane has been investigated A suitable apparatus is described and it is shown that the yield of gas is greatest when (i) the cathode is of nickel, (ii) the alkalinity of the solution is low, (iii) the current density is high By using the electrolytic March test with a standardised apparatus, 0 027 mgm of germanium dioxide can be detected S Ueno and H Ikuta Saturated fatty acids of chrysalis oil Palmitic acid is the main constituent of Japanese chrysalis oil, stearic acid and a saturated fatty acid of the C_{18} or C_{22} series have also been isolated

Co operation in Industrial Research

THE stimulating lecture on fundamental scientific problems in the food industry delivered by Dr L M Lampitt before the Liverpool and the Edinburgh Sections of the Society of Chemical Industry early this year directed attention to a number of problems in research which are of interest far beyond the bounds of the food industry Dr Lampitt for example was emphatic on the importance of the co ordination of research not merely of that financed or directed by the State but also of that carried out by academic or private institutions or by industry itself Through lack of such co ordination not merely in the food industry but in other industries as well there is overlapping and waste of effort and also failure to undertake some of the more fundamental work upon which progress finally depends

Dr Lampitt suggested that one of our most urgent problems is to explore the possibilities of effective co operation between the research stations research associations the universities and the industrial research organisations A survey of extra university research in pure and applied science has already been undertaken by the Association of Scientific Workers and should provide much useful data for the study of the possibilities of co operation The existence of duplication and the neglect of fundamental problems constitute powerful and sufficient reasons for an attempt to formulate a definite policy which would enable the greatest use to be made of each type of activity Such a policy in itself would ensure closer contact between the scientific investigator and the industrial world and would tend to eliminate any tendency for the former to work on problems which he considers to be of practical importance but which a representative of industry would easily demonstrate to be of no appreciable utility

The elimination of duplication and waste of effort even with existing resources should tend to liberate funds for fundamental scientific research, the position of which has already been seriously threatened by the restriction of the funds available for the Department of Scientific and Industrial Research As stated in the report for the year 1930–31 in curtailing such expenditure the policy of the Privy Council was to concentrate available funds on work of the most immediate practical value to industry leaving to happier times the expansion of work of which the results could only be available at some more distant date In the campaign which has since been undertaken to secure support for the research association scheme following on the exhaustion of the Million Fund, stress has been laid once more upon the work of the most immediate practical value, and the prosecution and endowment of fundamental and long range research have not received the attention which their place in the national economy demands Apart from this, although the Department has done much to encourage fundamental research in universities and other institutions, it has from the first attempted to induce industries to undertake work for themselves rather than to carry out scientific work for them or even to organise fundamental research

This position while general is fortunately not universal Certain of the research associations, for example have been and still are pursuing investigations of fundamental scientific importance, the application of which has yet to be demonstrated Other sections of industry have made their own arrangements for assisting academic research at the universities by a system of grants in aid of investigations on purely scientific subjects which are likely to contribute indirectly to the solution or understanding of industrial problems

As a prelude to such co operation it is essential that we should think out clearly the place and contribution of each variety of research organisation in relation to the economy of whole industries, and indeed of the national and not merely of individual industrial units or geographical or sectional interests It should not be too difficult a task, given a broad outlook and a spirit of good will and co operation, to elaborate a policy and devise a scheme which, while permitting full autonomy to individual research units should offer immense advantages in efficiency, economy, and the interchange and discussion of ideas and results among research workers It is unlikely indeed that under such conditions it would be necessary to create a fresh research institute or organisation The more efficient utilisation of funds already available, or a comparatively moderate expansion of expenditure within the framework of our existing organisation, should suffice to finance a good deal of fundamental research the prosecution of which is overdue

A further point made by Dr Lampitt relates to the broader distribution of purely scientific data collected in the research organisations of industry Even the smallest industrial research or analytical laboratory frequently acquires important scientific data and it is rare for such physical or chemical knowledge to be of commercial importance to the firm, or for its disclosure to play into the hands of a competitor If without disclosing the purpose of investigations of this type, means could be found of publishing the results a large amount of knowledge locked up in individual units of an industry could be made available, to the advantage not merely of particular industries but also of the industrial and scientific world as a whole It would, in fact, react to advantage and credit of those firms responsible for the work and would undoubtedly assist in the further and more efficient planning of our available resources

The illustrations cited by Dr Lampitt from the food industry were sufficiently suggestive, but they could easily be multiplied in such fields as analytical work chemical engineering and corrosion or in management methods Much machinery for co operative research already exists which might with advantage be used much more extensively in the exchange of information on non competitive matters Even in regard to the abstracting of chemical literature and information services, mistaken conceptions of individualism and independence still delay progress and make it difficult to achieve standards which are possible by co operation alone

These obsolete ideas are being steadily undermined by the work of various organisations, such as that of the British Chemical Manufacturers in regard to industrial safety, or of the British Standards Institution in the standardisation of materials and practice The development of habits of co-operation and encouragement of the exchange of information on common problems quietly fostered in this way should go far to overthrow ideas of trade secrecy which have prevailed too long With this, however, there is still need for a much fuller realisation of the place of research in everyday industrial practice Industries which plead inability to meet a heavier demand for support of their research organisation cannot in fact, expect much credence to be placed in their protestations, unless they can adduce evidence of a spirit of co-operation and of strenuous efforts to utilise to the maximum advantage by co-operation on such lines the organisations within their bounds already devoted to research

The Gas Referees and the Gas Industry

SCIENCE and industry are dependent for much of their progress on the existence and authority of master men to whom the less experienced and less endowed may turn for direction and advice. During periods of stress or emergency their value is readily recognised and their services eagerly sought; in normal times there is a danger that their existence may be forgotten because of their very modesty and the quiet and unobtrusive manner in which they work; but their presence in the background as an ultimate source of effective authority is essential. Those whom the community choose as such counsellors are men of wide experience, of outstanding ability: men whose word is accepted without question. Often they have retired from the routine of daily duty and, unencumbered by masses of detail, they are thus better able to see a problem in its entirety and to set it in the frame of their whole experience.

In the light of these considerations it is particularly regrettable that any community which in the past has been fortunate enough to possess such a source of counsel, should now contemplate its abandonment. The gas industry in Great Britain is a body which, for nearly seventy years, has possessed a source of inspiration and advice in the eminent men who have held the positions of Gas Referees and Chief Gas Examiner. Names such as those of Rucker, Tyndall and Harcourt, Williamson and Rayleigh, as past holders of these positions, coupled with those of the present gas referees—C. V. Boys, W. J. A. Butterfield, and J. S. Haldane—and the present chief gas examiner, Sir Richard Glazebrook, are in themselves evidence of the type of man who has given his services unsparingly in the interests of the gas industry.

The duties of the gas referees are to prescribe the places, times, apparatus and methods by which the gas is to be tested, and to determine if these tests are being carried out; they also decide the methods by which the apparatus employed is to be tested. Gas examiners, who have to make the tests, are appointed by the local authorities. The referees issue a general specification applicable to all undertakings and, where necessary, special specifications for any particular supply company. They also issue full and detailed descriptions of the apparatus to be used, much of which is the invention of Dr. C. V. Boys himself, and of the method of using this. All this is scientific work involving a knowledge of test methods and of the conditions of manufacture of gas.

The gas companies can appeal on certain points, and the chief gas examiner has to hear and decide the appeals. They can appeal against the specification, but we believe that there never has been such an appeal: nevertheless they value this privilege, and object to the Board of Trade, which is to make the specifications, also hearing appeals against them. They can also appeal against any particular test, and though usually the decision is easy, occasionally abstruse scientific questions are involved.

Such, in brief, are the chief duties of the gas referees and the chief gas examiner, and under their direction the routine business of gas testing has been ably conducted; but their services to the gas industry have been greater than any which could be prescribed by an Act of Parliament. Their real value and their real function have been those of counsellors. In the Gas Undertakings Bill which was recently introduced to the House of Commons, the proposal is made that the offices of Chief Gas Examiner and of Gas Referees should be discharged by the Board of Trade. There can be no doubt that the routine of gas testing, the collection of data relating to the gas industry, and similar routine work, can be efficiently and competently carried out by the civil servants to whom these duties may be delegated by the Board of Trade; but it is impossible that such civil servants, however efficient, can achieve that which has arisen from the eminence of the men who have previously been responsible for this work. The loss which the gas industry would incur by this change is beyond all computation.

It may be suggested, on behalf of the proposed change, that the replacement of the present holders of the offices would be no easy matter. Undoubtedly this is true, for eminent men are always scarce, but amongst present occupants of chairs of physics and chemistry at the universities of Great Britain there are men of outstanding merit who will, by the passage of years, be compelled to retire from active participation in academic work, and would be willing to place at the disposal of the gas industry the knowledge arising from their experience.

It seems incredible that the gas industry in Great Britain should wish deliberately to divorce itself from association with some of the ablest scientific men of the day. Must it not be that the change has been proposed without full consideration of the inevitable consequences?

Atomic Theory

The Atom By Dr John Tutin Pp 109 (London, New York and Toronto Longmans, Green and Co, Ltd, 1934) 6s net

ON the jacket of this interesting book appears the appetising paragraph 'No one interested in modern science should fail to read this book It deals with a problem of profound importance, and although written by a scientist for scientists the clarity and simplicity of the argument are such that the general reader fond of science will find it attractive as well as intelligible" On second thoughts this may not mean very much Science is a big subject and it is by no means certain that any scientific worker, writing on a scientific subject outside his own field deserves to be taken any more seriously than the layman I should not personally consider myself entitled to be regarded as a scientist writing for scientists" if I wrote a book on, say, biochemistry or mechanical engineering But such a claim is made for Dr Tutin, and being made, it is only fair to take it seriously On thinking over past and conceivable future indiscretions of this nature that I have committed or might conceivably commit, I am clear that the great danger for the professional, venturing into another branch of the profession, must always lie in the lack of an adequate background He may well provide exciting new ideas which may prove fruitful or unfruitful, but his critical discussion of current ideas is almost certain to be cruelly handicapped by lack of knowledge of what current theory can or cannot account for in its stride, and of what are the honest to goodness copper bottomed facts

We shall see that it is just here that Dr Tutin's speculation fails If he had known the facts and the present position of current theory, it is scarcely conceivable that he would have put his own alternative theory forward There is, moreover, another danger which, from internal evidence, Dr Tutin does not appear to have avoided—that of forming one's general opinion about the meaning of a theory almost entirely from popular and semi popular expositions without any study of more profound or more original sources Even when the popular expositors are such masters as Jeans or Eddington, this is highly dangerous The fare they provide cannot constitute a well balanced diet for a scientist It lacks the vitamins essential to growth

The thesis put forward by Dr Tutin in this book may be described in outline as follows, the description for distinction is printed in italics

(i) *The Rutherford Bohr model of the atom (for short the R B atom) was first put forward to explain the large angle scattering of α particles, which it did successfully on the assumption that the scattering is due to a small heavy nucleus carrying the charge + Ze where Z is the atomic number and e the (numerical) charge on the electron The same scattering law would be found if the nuclear charge were − Ze*

(ii) *There are grave deficiencies in the general theory based on the R B atom, partly philosophical (the failure of a strict law of causation) and partly practical Its obvious practical deficiencies are its failure to explain 'why some atoms emit light and others do not why some are electrical conductors and others insulators, why some are magnetic and others non-magnetic" (p 15) It fails also to explain chemical valency and chemical combination generally*

(iii) *Accepting the mathematical interpretations supplied by wave mechanics as to the fundamental nature and behaviour of protons and electrons (this is Dr Tutin's own phrase p 13) a much more complicated and satisfactory alternative atomic model can be put forward (for short the A atom) in which the nucleus is a collection of Z electrons and the outer atom contains all the protons and the other electrons (mainly grouped in subordinate structures of mass less than or equal to four) required to produce a neutral structure of the correct mass*

This is the foundation of the book in which Dr Tutin first attempts to specify these and other deficiencies in the current theory using the *R B* atom, and then to show how the *A* atom provides natural and simple explanations of these fundamental properties where the *R B* atom fails, and provides them, moreover, *without any infringements of a strict law of causation*

In his dislike of the law of causation Dr Tutin hates in good company It is a matter of taste about which no argument is necessary But Dr Tutin is wrong in attributing the failure of the law of causation in current theory to a weakness of the *R-B* atom This failure has nothing whatever to do with any special model, but is an inherent property of that very quantum mechanics the results of which Dr Tutin adopts to develop his *A* atom Here it seems he has been misled by his study of some popular exposition The failure of causation is, moreover, a far more refined concept than Dr Tutin appears to believe, and enters quantum mechanics (as the uncertainty principle) only because quantum mechanics, unlike Newtonian mechanics, does not permit of absolutely precise initial conditions ever being laid down in any problem To the degree of precision permitted by the initial conditions the state of affairs at any later time follows as rigorously and uniquely as ever it did in Newton's day To the objection that if quantum mechanics imposes this restraint it is to that extent a bad mechanics the answer is, of course, that only by imposing this restraint can quantum mechanics account for the *diffraction* of electrons by a regular lattice and that, in spite of the unexpected nature of the restraint, quantum mechanics can still in principle predict the results of any conceivable experiment The phenomenon of electron diffraction, which is independent of any particular atomic model, is not discussed by Dr Tutin, presumably for this very reason that diffraction will appear just the same whether the actual atoms are *R B* atoms or *A* atoms This is true enough But the phenomenon disposes of any claim that his theory is either more or less causal than current theory, and the whole of his remarks about the law of causation seem to me to be beside the point

Let us now return to the main thesis that the *R B* atom, plus quantum mechanics is a failure in the regions of physics and chemistry already mentioned and that the *A* atom succeeds at least qualitatively everywhere, without surrendering but rather incorporating whatever successes the *R B* atom has had

If quantum mechanics with the *R B* atom had done no more than Dr Tutin thinks it has done it would certainly be highly vulnerable to his or any other attack But this is far from the truth To take first the question of electrical conductivity —that is, of forming a metal or an insulator in the solid state It has been shown in detail just what conditions must be satisfied for the solid state to be a metal, and in particular it can be rigorously deduced from the *R-B* atom and quantum mechanics that the alkalis must be metals and not insulators The proof can probably be extended to the noble metals Owing to the complexity of the problem it has not yet been rigorously proved that, for example, diamond is an insulator This is to be regretted, of course, but in a qualitative way the solution is already complete enough It is merely the numerical computations which cannot be carried through The qualitative solution extends also to include the queer substances now called semi conductors the conductivity of which increases sharply with temperature Boron, if its properties are correctly described by Dr Tutin, is such a substance, but the classical example is cuprite

To turn to magnetic properties it is again hard to see that qualitatively the current theory fails in any way Qualitatively and even quantitatively, the paramagnetic properties of the rare earth salts are completely accounted for The ferromagnetic properties of the iron group are already accounted for in the sense that using only quantum mechanics and the *R-B* atom, and without any *ad hoc* hypothesis, it can be shown definitely that ferromagnetism will occur when certain possible conditions are satisfied, and in a general way that these conditions might be most easily fulfilled among the metals and alloys of the iron group It is not, however, yet possible to say quantitatively that such a metal or alloy will be ferromagnetic and such another one not[*]

In the optical and X ray field the success of the *R B* atom is of older date, and is not called in question by Dr Tutin except that he maintains that an explanation is required why some atoms, particularly oxygen and sulphur, have a spectrum difficult or impossible (*sic*) to excite I do not think that there is any difficulty here which calls for an explanation so ruthless as Dr Tutin's, whose *A* atoms for oxygen and sulphur contain no free' electron In fact, Dr Tutin explains too much, for he forgets that conditions of excitation are all important When left to itself, even the stubborn oxygen atom emits light, so much so that no spectrogram of the light of the clear night sky can be taken without showing the oxygen atom s auroral green line, while the lines of oxygen and sulphur in several states of ionisation are familiar features of the spectra of the hotter stars

Finally, in the chemical field the qualitative successes of quantum mechanics and the *R-B* atom seem even more striking, and the promise of more quantitative success is rapidly being fulfilled Current theory preserves and explains naturally the fundamental differences between covalent and electrovalent bonds, and accounts also perfectly satisfactorily for the number of possible covalencies—why a covalent link saturates in fact and cannot take part strongly in any further union Complicated as the calculations are, the theory can even account in a general way for the stereochemistry of carbon and why it is unique Two quantum mechanical *R-B* atoms of suitable valency have, in short, in current theory the means to unite and the urge to do so, Dr Tutin's statements to the contrary notwithstanding, the means to unite being an unpaired electron on each and the urge that by uniting with the formation of a new electron pair they can form a state of lower energy

---

[*] In all this field of the atomic theory of solids an excellent account of the existing state of current theory will be found in the article by Sommerfeld and Bethe in the Handbuch der Physik', Vol. 24, Pt. 2 (Second Edition)

To sum up this survey of fields touched on by Dr Tutin, bearing in mind evidence from other fields, such as collision theory, on which he does not touch, it seems fair to say that quantum mechanics working on the basis of the *R B* atom promises to be completely competent to embrace in one simple theory the whole range of ordinary physics and chemistry The whole general structure of the periodic table of the elements is explained in this way without any further hypothesis There is no mystery about the periods $2n^2$ They are necessary logical consequences of the theory, which among other things allows only one electron to occupy any one state of given quantum numbers Phenomena which with the *R B* atom are classed as nuclear physics are at present excluded from this range When we come to nuclear properties, though much success has already been achieved by the application of quantum mechanics to the heavy particles in the nucleus, the prospect is not so clear, and great modifications may be necessary before much further progress is made It is well to emphasise finally with what beautiful economy of assumptions all this success can be achieved We require nothing but quantum mechanics applied to electrons and heavy nuclei of charges 1–92, interacting with their ordinary Coulomb forces, nothing less and nothing more (except perhaps patience !)

What has Dr Tutin to offer us in place of this elegant and well co-ordinated theory in which the diverse properties of, for example, C, N and O seem to find a natural place and to be referable, surprising as it may seem to the slight change of one more electron and one more nuclear charge from one atom to the next ? If it were as yet only one tenth as successful, his theory would be worthy of the most elaborate exploration The *A* atom has a light nucleus with charge $-Ze$ with the protonic masses at various distances in orbital motion round it, but so *rigidly* (*sic*) bound to it that the nucleus reacts like a body of atomic mass to any passing α particle This rigid binding is referred to a quantum mechanical restraint Since Dr Tutin's quantum mechanics is our ordinary quantum mechanics we can inquire more closely into this, which he has omitted to do Extra rigidity of this type is found, for example, when electrons bombard atoms, but only when the energy of the bombarding particle is less than the energy of binding Dr Tutin must, therefore, assume new binding forces other than Coulombian to tie the protonic complexes to the nucleus so that their energy of binding may be of the order of 10^7 electron volts at least Non Coulombian forces are also required to enable quantised orbits of heavy particles to be of atomic and not nuclear dimensions (10^{-8} cm rather than 10^{-12}) This is a grave inelegance in his theory, but let us allow these forces and proceed to inquire how such a structure, allowed to be rigid, will scatter α particles

When an α particle passes near the nucleus it will be scattered by the usual Rutherford scattering law with a factor Z^2 for the nuclear charge Ze Note that the extra forces are now ignored and the scattering purely Coulombian ! When it passes near one of the protonic complexes it will also be scattered by Rutherford's law with a factor P^2 when the charge on the complex is Pe This extra scattering has been overlooked by Dr Tutin It does not occur for the *R B* atom because the electrons are light and not rigidly bound to the nucleus, so that they take no part in the large angle scattering This extra scattering must be added on for each protonic complex The resultant scattering will be given by Rutherford's law with the factor $Z^2 + \Sigma P^2$ instead of Z^2 Dr Tutin's model gives a factor sufficiently greater than Z^2 to destroy the agreement between theory and experiment for the scattering of α particles by elements of medium atomic weight The alternative atom fails outright, self strangled at birth

If this point is ceded on the ground that experiments have not established for certain this rather fine distinction, we fall at once into all sorts of terrible difficulties with isotopes For example, lithium consists of two isotopes, Li^6 and Li^7, of which, according to Dr Tutin, the latter contains one free electron and is therefore a metal and the former none and is therefore presumably an insulator, though Dr Tutin does not say so explicitly (A slight conductivity in silicon is attributed to the possession of a free electron by its second isotope, p 57 !) Since deposits of Li^6 and Li^7 can now be obtained separately, it might be interesting to Dr Tutin if experiments were made to determine their separate conductivities, though I doubt if any other chemist or physicist would expect any significant difference between them To chemists in particular, differences so striking between the isotopes of a single chemical element are quite unbelievable, and their disbelief is amply warranted by all the available evidence Since isotopic differences in general are referred by Dr Tutin to the outer rather than the inner structure of the atom—definitely so for light elements—the chemical resemblances of isotopes can only be maintained by unnatural *ad hoc* hypotheses Finally, of course, his theory requires us to refer radioactive properties to the outside rather than the inside of the atom

It would be ungracious to pursue further Dr Tutin's attempt to substantiate the *A* atom He is continually involved in *ad hoc* arguments, which he rightly deplores when he thinks others have used them, as in the explanation with the *R B* atom of the periodic table (p 30) There is in fact nothing *ad hoc* in this His attempted explanation of Moseley's diagram of characteristic X ray lines seems to me shaky in the extreme and looks perilously like invoking a denial of the conservation of energy But this may be doing him an injustice At no point is there any indication that quantum mechanics applied to the models he proposes with some specified law of force between the various parts would give the results he postulates No such law of force, which cannot be Coulombian, is ever specified All his results are just pious hopes and no more, and most of them are demonstrably wrong

Why then review at such length what is here stated to be in the reviewer's opinion entirely without substance ? There seem to be reasons of some cogency In the first place the appearance of an essay such as Dr Tutin's forms a natural occasion on which to overhaul the present position of current theory and do some stocktaking in public Again no physicist who has worked as such during the last twenty five, or even the last fifteen, years should be surprised by any extravagance in the development of physical theory or be unprepared to accept changes even more revolutionary still Nothing could have exceeded the apparently wild extravagance of de Broglie's first work on electron waves which led directly to quantum mechanics Experiments in thought such as that of Dr Tutin must be made and made welcome just because they are experiments, and must not be condemned out of hand But just because the current theory of the outer atom is a successful and flourishing theory, much must be required of any rival that could supplant it, and Dr Tutin's theory cannot stand the pace It must be discarded after examination, not because it is counter to current opinions, but because it is not internally self consistent and does not correlate with sufficient elegance a wide enough range of physical and chemical facts There is also one further reason remaining Dr Tutin's theory has been rather widely noticed in the non scientific Press, where it has sometimes been discussed as if it were an accepted theory—a revolutionary overturning of current views—but alas it is far less momentous Physical theory has undergone such striking and successful revolutionising in recent years that such Press notices can perhaps scarcely be avoided It is all the more necessary that, when a would be revolution, widely heralded, fails utterly, its masquerade as a success should be reduced to the shortest possible limits

The Mitten Crab in Europe

Zoologischer Anzeiger Herausgegeben von Berthold Klatt Zugleich Organ der Deutschen Zoologischen Gesellschaft Ergänzungsband zu Band 104 *Die chinesische Wollhandkrabbe* (Eriocheir sinensis *H Milne-Edwards*) *in Deutschland* Von Dr Nicolaus Peters und Dr Albert Panning Mit einem Beitrag von Prof Dr W Schnakenbeck Pp viii + 180 (Leipzig Akademische Verlagsgesellschaft m b H , 1933) 11 60 gold marks

THE invasion of European inland waters by a Chinese river crab which has been in progress for more than twenty years has hitherto attracted little notice from zoologists in Great Britain There is, however a distinct possibility that the invasion may spread to our rivers and that this undesirable alien may establish itself as a member of the British fauna It is therefore desirable that attention should be directed to the exhaustive monograph which has just been published by Dr N Peters and Dr Albert Panning with an appendix by Dr W Schnakenbeck The species is now being used as an easily obtainable type' and as a subject for experimental work in many German laboratories The full and clear account of its morphology and development which is given in this monograph will therefore be very useful In addition, the history of its appearance and spreading in Europe is recorded in detail with full particulars of the damage it causes and with suggestions for its utilisation as food for man and domestic animals.

Eriocheir sinensis is known in Germany as the *Wollhandkrabbe* from the fact that the pincer claws are clothed with long soft hairs, and a writer in the *Times* has suggested 'mitten crab' as an appropriate name for it. It belongs to the family Grapsidæ and, like many of its allies, it is characteristically an inhabitant of brackish water, ascending rivers for long distances in fresh water but returning to the estuaries to breed.

The mitten crab must have been introduced into German rivers before 1912, for in that year a specimen was found by a fisherman in the River Aller, a tributary of the Weser. The specimen was fortunately preserved, although it was not identified until many years later. In 1923 the species was found to be established in the lower reaches of the Elbe and was determined as *Eriocheir sinensis*. Since that time it has become progressively more abundant in the Elbe and the Weser, and it is now caught by the hundredweight at certain seasons in the nets of the fishermen. It has penetrated inland as far as Berlin and even Prague, and has extended its range to the Rhine and the rivers of Holland on one side and to East Prussia on the other. In some localities it has become a very serious menace to the fresh water fisheries, stealing the bait from the hooks and cutting and ruining the nets. It is also stated to damage the muddy banks of rivers by burrowing in them.

The means by which the mitten crab found its way to Europe remain something of a mystery. Dr Peters discusses various possibilities and comes to the conclusion that it was most probably carried in the water ballast tanks of some vessel trading with the Far East. If so, there is no reason to suppose that such an incident might not happen again or that the mitten crab would find in the Thames a less favourable environment than in the Elbe and the Weser. Further, since the adult crabs seem to be equally at home in sea and in fresh water, it will be surprising if they do not succeed sooner or later in crossing the North Sea.

In view of the attempts that are being made to popularise in Germany the use of the mitten crab for human food and for feeding pigs and poultry, Dr Panning directs attention to the fact that in the Far East the species is known to be one of the intermediate hosts of the lung fluke, *Paragonimus*. He points out, however, that owing to the absence from Europe of the species of water snails which are the first hosts of the worm in question, its spread in Europe is most unlikely, and since the crab would only be consumed in the cooked condition, no danger from it is to be apprehended.

The accidental introduction and spread of animals and plants in countries where they are not native is unfortunately common enough, but there are not many instances of aquatic animals being transported unintentionally from one country to another. The case of the mitten crab is therefore of some theoretical, as well as practical, interest.

Short Reviews

Pharmaceutical Formulas. Vol. 2. *Being the Chemist's Recipe Book of Formulas for Adhesives, Beverages, Cleaning Materials, Culinary and Household Requisites, Horticultural and Agricultural Preparations, Inks, Lozenges, Perfumes, Photographic Preparations, Polishes, Soaps, Toilet Articles, Varnishes, Veterinary Preparations, etc., including numerous Descriptions of Practical Methods employed in their Manufacture and other Information of use to Pharmacists and Manufacturers*. Tenth edition, entirely revised and rewritten by G. P. Forrester. Pp. xx+983. (London: The *Chemist and Druggist*, 1934.) 15s.

"PHARMACEUTICAL FORMULAS", which appeared as a first edition in 1898, is a collection of formulæ of both old and new preparations of interest not only to pharmacists, but also to other manufacturers of articles and preparations of allied types. With the increasing scope of the book, it has been deemed necessary to publish the tenth edition in two volumes, vol. 1 being essentially pharmaceutical and medicinal, whilst vol. 2, now under review, has collected those formulæ of more general and varied interest, such as cosmetics, perfumes, polishes and horticultural and agricultural preparations such as fungicides and insecticides. These sections are but a few of the many varied ones, but they probably constitute those in which the greatest advances have been made in recent years.

The last two decades have seen an enormous increase in the demand for toilet preparations, such as face powders, creams, lipsticks, etc., each with so many varieties that their preparation now requires considerable skill and knowledge. Moreover, fashion would appear to maintain them in popularity, and with ever-varying design and purpose, so that the manufacturers must of necessity keep pace and satisfy the demand. The advent of the cellulose finished motor car body has led to the demand for hard high gloss polishes with a quick effect, which demand has resulted in a large number of new types of formulæ

The proof however, of the value of a book of formulæ lies not only in the ingredients but also in the description of the exact working conditions and correct manipulation without which most technical formulæ are useless The book does appear to satisfy this requirement, and moreover each section is preceded with a monograph discussing the development and modern requirements of the preparations concerned H B

A Bibliography of Sir James George Frazer, O M Compiled by Theodore Besterman, with Portraits and Facsimiles and a Note by Sir J G Frazer Pp xxi+100+3 plates (London Macmillan and Co, Ltd, 1934) 12*s* 6*d* net

THIS bibliography of the works of Sir James Frazer has been produced by the subscription of friends and admirers and under the ægis of the Folklore Society in celebration of his eightieth birthday in January last The work of Sir James Frazer is too well known for this list of his books essays, lectures and addresses to call for extended comment It chronicles a remarkable achievement It may, perhaps come as a surprise to those who are not intimately acquainted with the extent and variety of his writings to find that although The Golden Bough" bulks large, it by no means expresses the whole of his interests nor notwithstanding its many editions, has it absorbed one tithe of the apparently boundless store of energy upon which he has drawn in the fifty five years of his life as an author The Golden Bough is extensive enough to have been the life work of any ordinary individual—assuming that he had the genius to conceive it Yet Sir James in his Totemism and Exogamy", his 'Folklore of the Bible" and his study of immortality has produced three major works, any one of which would have taxed the industry and made the reputation of a research worker

The bibliography has been admirably produced and is illustrated with excellent portraits of Sir James and with facsimiles which show his method of working The first page of the list is marred by a misprint, the editor having fallen into the familiar schoolboy trap of 'Cataline"

The Woodlands and Marshlands of England By H A Wilcox (Mrs G S Treleaven) Pp 55+2 maps (Liverpool University Press of Liverpool, London Hodder and Stoughton, Ltd, 1933) 6*s* net

THE University Press of Liverpool has recently published two maps of the woodlands and marsh lands of England prepared on the researches of H A Wilcox These are founded on several years of research which was assisted by the British Association The first map is founded on geological, climatic and topographical evidence, and the second is drawn from the evidence deduced from early literature To these have been added a discussion of the problems involved and of some of the regional questions The first map involved considerations of the underlying rocks and their soil covering, of the surface configuration of relief, height and aspect, and of the climatic conditions, which as yet are not sufficiently determined even in the immediate past But all three of these act together or in opposition, to provide the area which was woodland covered or heath or bare grassland Then again, woodlands may destroy themselves by the accumulation of their decaying materials and by holding up water, changing lands into marshes Many areas can be only tentatively mapped, awaiting the local research of counties The corrections made thereby are essential to this study, and it is requested that they be communicated to Prof Roxby of the University of Liverpool The subject is an important one, for it is basal to the study of early man in Britain, determining his track ways and early settlements

Grundriss der physikalischen Chemie Von Prof Arnold Eucken Vierte Auflage Pp xxiii+699 (Leipzig Akademische Verlagsgesellschaft m b H 1933) 29 gold marks

THE third edition of Eucken's Grundriss der physikalischen Chemie' was merged in a Lehrbuch of 1,000 pages, issued in 1930 (NATURE, Dec 27 1930, p 988) but even then the project existed of splitting the product into two parts, the more general and elementary part being issued as a fourth edition of the Grundriss" and the more special and advanced part as a second edition of the 'Lehrbuch" The first portion of this project has now been carried out, and has yielded a volume of 700 pages with 179 instead of 250 figures The tables and figures have been taken for the most part from the 'Lehrbuch", but the text has been condensed by omitting much descriptive matter (for example, Aston's mass spectrograph) and concentrating on fundamental laws Numerical exercises have also been added at the ends of certain chapters

Science and God By Bernhard Bavink Translated by H Stafford Hatfield Pp ix+174 (London G Bell and Sons, Ltd 1933) 5*s* net

IN recent years, fundamental changes have taken place in all the assumptions upon which philosophical and religious discussions are based The author makes the point that mechanistic physics by no means implies atheism and materialism as a necessary consequence, and that the so-called neutrality of science with regard to religious questions is no more an axiom of procedure In fact, the old materialistic arguments, still put forward in free thinking circles will be found to be out of date doctrines in the light of a correct interpretation of the results of present day science T G

Germination of Seeds*

By SIR ARTHUR W. HILL, K.C.M.G., F.R.S.

THE ovule, which later becomes the seed, is enclosed in the fruit vessel or ovary, the covering provided by the mother plant. During its development, the offspring is protected and nourished by its mother, and the ovule gradually develops into the seed, with its own protective skins or coats, lying within the enlarged ovary, which in the course of time has become the fruit.

Examples of fruits with their contained seeds are such familiar objects as the fleshy fruited tomato with its dry, flat seeds, the broad bean or the scarlet runner with the enclosed seeds or beans, and the Brazil nut where the mother plant has provided a thick, woody, cannon ball like protective fruit—which can only be broken by a powerful hammer or cut across with a saw—enclosing the well known hard shelled 'nuts'.

Many seeds have been so well protected by the mother plant that the liberation of the seeds contained in the fruit is often a matter of some difficulty. The Brazil nut fruit is perhaps the most remarkable example. In other cases, however, the seeds are shed or scattered from the fruits with the greatest ease when the fruit is ripe, as any gardener knows only too well who attempts to save seed of an *Impatiens* (balsam) or collect the seeds of gorse, which are shot out from the fruit as if from a catapult. The horticulturist, of course, is concerned only with the seeds when he wishes to replenish his stock of plants. In the majority of cases he merely sows the seed, and germination, that is, the escape of the embryo from the protective seed coats, takes place sometimes in a few days, sometimes after some weeks from sowing. In the case of willows and poplars the seed will germinate the day after it is sown, and if the minute seed should be kept for more than a few days it will completely lose its power of germination. In other cases seeds may remain viable for years. I remember well the late Sir Michael Foster showing me a pot of *Iris*, in which the seed was just beginning to germinate fourteen years after it had been sown! Then there are the seeds of the Australian wattles (acacias) which rarely germinate until a fire has passed over the ground in which they are lying, or which, if sown at home, have to be scraped with a file, or treated with strong sulphuric acid, as is also the case with some other seeds, in order to induce germination, so strong and resistant is the seed coat. It is known that seeds of *Acacia lophantha* will germinate after being stored for sixty-eight years and recently, in connexion with inquiries as to seed vitality, we have experimented at Kew with seeds long stored in bottles in our Museum and have successfully germinated seeds of *Anthyllis vulneraria* and *Trifolium striatum* both ninety years old, and seeds of four other leguminous plants, including the Spanish broom (*Cytisus scoparius*), all eighty one years old.

How long the poppy seed, which germinated and flowered so wonderfully after the shelling of the Somme battlefield, had lain buried in the soil, or how long charlock seed will remain living when buried, we do not really know; but it is truly remarkable that life can persist for so long a time in a body so minute as the embryo of a seed imprisoned within its seed coats, when the seed is preserved under suitable conditions. What the nature of such life may be, and to what extent respiration and the other functions we associate with living matter, may be carried on in dormant seeds, is scarcely within the scope of my text, nor could I throw much light on this arresting problem. For the moment we are concerned with the embryo prisoner, whether serving only a brief or a long sentence of confinement, and the nature of the prison.

There is a minute orifice in the seed, the micropyle, originally the point of entry of the pollen tube into the ovule, behind which ultimately the radicle or root tip of the embryo will lie in the mature seed. Through this minute and well-sealed pore, and also by absorption through the coats, moisture enters the seed when conditions become favourable for germination, and the radicle emerges at the micropyle. In the case of most seeds it is safe and usually advisable to store them through the winter and sow them in the spring, since the embryo is in the resting or dormant condition, whatever that may signify. There are, however, a few seeds which do not undergo any resting stage, but development is continuous, and the embryo is in an advanced stage of germination when the seed is shed. The prisoner effects his escape, as an Irishman might say, before he has been shut up! Willow seeds, as I have mentioned, almost come within this class, but the mangrove, with its viviparous seeds, is a classic illustration. Here the seed in the inverted pear-like fruit germinates while the fruit hangs on the trees. The long fusiform radicle grows downwards and eventually the young plant falls off into the water where it floats upright and gets carried to a safe landing in the mud of a tropical estuary. *Typhonodorum*, a giant aroid from Madagascar, behaves in a similar manner, and well-developed young plants, still attached to the large, bean-like seeds, are shed into the water where they float upright with the young leaves in the air.

In these cases, we might say that the embryo, realising how flimsy and insecure are its prison walls, considers it wiser to escape at once and so avoid the risk of being killed by insufficient protection, which might have happened should it have 'gone to sleep' for a period, like other embryos, after the maternal influences had ceased

---

* From the Friday evening discourse entitled 'The Escape of the Prisoner: Studies in the Germination of Seeds' given at the Royal Institution on November 3, 1933. A fuller account of the devices here described with illustrations will be found in *Annals of Botany*, 47, 873, Oct. 1933.

The normal seed consists of two close fitting coats, the inner usually membranous, the outer being either papery, leathery or woody, and often ornamented with most beautiful surface markings which cover and protect the embryo The embryo may be embedded in food material on which it can draw when germination commences—the type known as albuminous—or it may have absorbed into itself, during its development, all the nutritive materials supplied by the mother plant and stored them for future use in its seed leaves or cotyledons —which is known as the exalbuminous seed In either case germination, with the majority of seeds is simple and straightforward the emergence of the radicle, the splitting open of the seed coats and the withdrawal of the cotyledons or seed leaves follows in due course In a few cases, of which the vegetable marrow (*Cucurbita*) is a good example, the young seedling takes special care to free itself from its seed coat and develops a special peg like outgrowth at the apex of its young root which presses on the lower valve of the seed coat while the arch of the young stem carrying the cotyledons lifts up the upper valve and so effects its escape The youthful prisoner thus puts its foot on the floor of its prison house and raises the roof with its bent shoulders

The palms show certain peculiarities in the germination of their seeds, which are unlike those of other plants I will take the familiar date stone (*Phœnix*) as my example Dates are fleshy fruits with a hard horny like stone in the centre, which is the seed In the middle of one side of the seed there is a small circular umbilicus or navel behind which lies the embryo Owing to the horny nature of the endosperm of the seed, it would be well nigh impossible for the embryo to escape if the date attempted to germinate in the usual way since the cotyledon and shoot apex could not get free from the seed, even though the root could grow out and push down into the ground The problem is solved by the date, coco nut, double coco nut and other palms by transporting bodily the whole embryo out of the seed through the navel-like depression and burying it in the ground some distance below the surface of the soil This is accomplished by the outgrowth of a closed germ-tube, the cotyledonary sheath, completely surrounding the embryo, which in the double coco nut is a stout formidable looking article Though the embryo has been taken out of the seed however, and is being nourished by the supplies contained in the seed through the cotyledonary sheath or tube, the problem of its escape is not yet solved, since it is still a prisoner within its own tube like sheath It is as if the walls of its prison cell had become elastic and extensible and the cell had extruded itself through its window, carrying the embryo still imprisoned within the elongated cell, a procedure which may be compared to a person sliding down a tubular fire escape from a window

The embryo, however, is able to solve the problem for the young shoot with its seed leaf grows and forces its way through the wall of the germ tube and emerging into the air finally starts on an independent existence This may take place in a fairly short time, but in the case of the double coco nut several months elapse after the embryo is carried out of the seed before the young palm leaf of the seedling escapes into the daylight The coco nut and double coco nut differ a little from the date in that the actual seed is enclosed in the innermost wall or endocarp of the fruit, and are thus similar to cases I am about to describe, otherwise the procedure is exactly like that exhibited by the date

Turning now to those seeds which have an additional protection in the way of part of the fruit wall as well as their normal seed coats as in the coco nut to which I have just referred I may mention first the more simple cases of plums, cherries almonds and olives In these cases the edible flesh is part of the 'fruit' proper but the stone is also a portion of the fruit wall, so that it is not strictly correct—botanically—to speak of plum or peach stones or coco nuts as 'seeds', since the stone is a fruit structure and only the kernel is the actual seed

The fruit wall or pericarp consists of three layers or coverings the outer one which is the skin the middle fleshy and edible portion the mesocarp, and the hard innermost layer, the stone or endocarp which encloses the seed or seeds Stones or stony endocarps of this nature may contain one, two or several seeds

Cherry or plum stones afford good examples of stony endocarps containing a single seed, and the embryo has not only to solve the problem of escaping from its seed coats, but also the more difficult task of getting out of the woody box like stone, which has to be cracked by hand should one wish to obtain the kernel

Careful examination of a plum stone shows the endocarp to consist of two similar and closely united halves only separable when the plane of weakness becomes softened The cells of the stone do not cross the line of junction of the two halves of the stone, but are turned at right angles at the median line and the two distinct halves are firmly 'cemented' together The stone thus easily splits into its two halves, after sufficient moistening by the pressure exerted by the emerging radicle or root tip of the embryo, and in due course the cotyledons or seed leaves with the young shoot apex between them are successfully drawn out from the seed coats and enclosing stone, and expand in the air

The walnut, *Juglans*, the shell of which again is a fruit structure behaves much like the plum on germination, the shell splitting into its two component halves Here, however, there is the difference that the shell is formed by the close adhesion of two carpels each half of the shell being a separate entity

(To be continued)

Mitogenetic Radiation and Bioluminescence

By DR J B BATEMAN

THIS article is occasioned by recent popular descriptions [1] of an apparently well attested case of luminescence in a human being in Italy and the references to mitogenetic radiation which accompany them The subject is a woman suffering from asthma She is psychologically abnormal —intensely religious and hysterical—and the phenomenon of light emission occurs during light sleep in circumstances which suggest that it is connected with these abnormalities It lasts about three seconds is of sufficiently high intensity to be photographed with an exposure of one sixteenth of a second and is accompanied by increased respiratory movements greatly increased pulse rate and by the utterance of moaning sounds and expressions

The phenomenon is certainly unusual The Italian peasants are said to regard it as a manifestation of holiness Signor Protti[5] attributes it less picturesquely and perhaps less correctly to the action of blood radiation in causing luminescence of certain substances in the skin Protti s explanation is very unconventional for bioluminescence is generally supposed to be a type of chemiluminescence produced during the oxidation of certain substances the luciferins in presence of enzymes known as luciferases[6] Naturally this mechanism has not been demonstrated in the rare cases of luminescence in human beings but one would hesitate to accept an entirely different kind of explanation without strong positive evidence in its favour It is possible that some instances of human luminescence are due only to infection by luminous bacteria

The casual references to blood radiation are presumably intended to imply that the existence of such radiation is firmly established and its nature quite generally known This is not the case The fundamental experiment of Gurwitsch claiming to show the emission of radiation from an onion root tip which could stimulate mitoses in a second root placed near it has been and continues to be subjected to severe criticism Indeed the state of the subject at present makes a final decision with regard to the validity of this experiment quite impossible This uncertainty has not however deterred Gurwitsch and his pupils from an elaborate development of their ideas both experimental and speculative unfortunately there are contradictions at almost every stage

The supposed identity of the radiation with short wave ultra violet light fundamental to the most important later experiments itself rests on contradiction the resolution of which should have been the primary object of later research Thus although behaving in certain experiments like ultra violet light (being transmitted by quartz and absorbed by glass etc) mitogenetic radiation can pass without being significantly absorbed along the interior of an onion root or through a considerable thickness of a suspension of yeast in beer wort Further there is no agreement with regard to wave length Gurwitsch[7] by experiments with filters and by spectral dispersion of the radiation found a wave length 190–250 mμ Reiter and Gabor[8] by the same means found 340 mμ and both sets of workers were able to confirm fully their own conclusions by experiments with ultra violet light from artificial sources Ignoring or explaining away these very serious discrepancies Gurwitsch continues to regard mitogenetic radiation as ultra violet radiation of wave length 190–250 mμ

If this contention is correct it should be possible to detect mitogenetic radiation by purely physical means but satisfactory evidence is unfortunately lacking Positive results obtained with a photosensitive form of the Geiger Muller electron counter[9, 10] the most sensitive apparatus available are offset by several negative results[11, 12] and the latter also demonstrate how easily spurious positive effects can be obtained if experimental conditions are not properly controlled The most recent experiments[13] suggest that mitogenetic radiation if it exists cannot be detected by any known physical method its intensity is certainly less than about 300 $h\nu$/cm ^{2} sec

There is no space for a more detailed discussion some quite characteristic points have already been referred to in NATURE[14] and a detailed review will appear elsewhere[15] It is only important for the present to note that references to mitogenetic radiation and with them Protti s reference to blood radiation should be regarded with scepticism Even if mitogenetic radiation exists it is almost certainly too feeble to be capable of causing emission of visible fluorescence Protti s explanation for his remarkable case of bioluminescence is therefore to be rejected

Obituary

CARL OLOF LUNDHOLM

CARL OLOF LUNDHOLM who died on May 8, at the ripe age of eighty four years, was born in Sweden in 1850 His father was Court Quartermaster and had filled this important office, which however is now extinct, to four of Sweden's kings He was what we would now designate a chemical engineer, though the term was then not known Through the personal influence of his great fellow countryman, Alfred Nobel, he obtained facilities for studying the manufacture of fulminate of mercury in a French factory on the outskirts of Paris Largely as the result of this special knowledge he was invited to join the staff of the Nobel Explosives Co , Glasgow, in 1878

This company, which was brought into being to exploit Nobel's discoveries in the realm of high explosives, had at that time established two factories in Scotland one at Ardeer, Ayrshire, where nitro-glycerine explosives were made, and another at Polmont, Stirlingshire, where detonators were made Both of these branches of manufacture were at that time extremely hazardous and accidents were fairly frequent With both of them Lundholm became intimately associated and on both he left the impress of his strong and courageous personality He was most assiduous in improving the safety factor while increasing efficiency, and the industry to day, considered from the world point of view, is a monument to his ingenuity and foresight This, indeed, is generally recognised, even though the great public never knew very much about him, as he never courted publicity in any shape or form

Lundholm became manager of the Ardeer factory in 1889 and retired from that position in 1909 to become technical adviser to the Nobel Dynamite Trust, with headquarters in London On the outbreak of the War this Trust automatically came to an end, as did also Lundholm's thirty-six years' intimate association with the high explosives industry But even in his retirement he maintained his interest to the very end, and though in later years afflicted by blindness, he kept up a world wide correspondence with old and new friends associated with the industry Indeed, until a few days before his death, he was actively engaged on the writing up of his early experiences in the development of high explosives

Although Lundholm was a member of many societies, he was not a writer of papers, though he inspired many On the other hand, he did recognise the value of research, and with the encouragement of his board, he inaugurated what was probably the first research laboratory in the British Isles His name appears fairly frequently, too, on patent specifications

Lundholm was known to everyone in 'explosives' circles, and during his period of management at Ardeer he must have had thousands of callers from all over the world By those of them who are still alive, his loss will be keenly felt, for he was a kindly soul and was always ready to help and encourage young men He was, however, a stern but just disciplinarian and in times of danger, and these were not infrequent in the early days, he was cool and collected and always master of the situation

WILLIAM CULLEN

THE REV J H HOLMES

JOHN HENRY HOLMES, who died on April 19, was born on June 19, 1866 Having been ordained in 1893, he was appointed by the London Missionary Society at first to the Fly River District, Papua, and a year later to the Elema District (Gulf of Papua) , he settled at Jokea in November 1894 In 1897 he removed to Orokolo, and in 1910 he finally settled at Uriki in the Purari Delta He left Papua at the end of 1917 and, having retired from active service, returned to England in 1920 Thus for more than twenty years "Homu" laboured among two of the most interesting of the peoples of the 'Papuan' stock, about whom previously there was but scanty and often erroneous information

Mr Holmes had a genuine regard for and sympathy with his people, and he recognised that, in order to understand their point of view, it was first necessary to have a thorough command of their language and then to study their customs and beliefs He wrote short papers on the initiation and religious ideas of the Elema tribes (*J. Anth Inst* , 418–431 , 1902), on their distribution and history (*J Anth Inst* , 125–134 , 1903), on their totemism and social conditions (*Man*, Nos 2 10 , 1905) and on their toys and games (*J Roy Anth Inst* , 280–288 , 1908) He also published a preliminary study of the Namau language, Purari Delta (*J Roy Anth Inst* , 124–142 , 1913) It was not until 1924 that he collected his observations in a book on a comparison of the Purari and Gulf natives ("In Primitive New Guinea') Finally, in 1926, he published "Way Back in Papua", in which he attempted in narrative form to give a picture of the old native ways of looking at things and of the effects of the introduction of Christianity

Unfortunately, Mr Holmes had received no scientific training, so there is a lack of precision in many aspects of his work , nevertheless, he has given us very valuable accounts of the ethnography of his two areas, and thus he takes an honourable place among those missionaries who have materially added to our knowledge of backward peoples

A C HADDON

SIR MAX MUSPRATT, Bt

THE public career of Sir Max Muspratt, who died on April 20 at the age of sixty-two years, is very well known He was the third generation of a family of chemical manufacturers His father, the late E K Muspratt, built the Muspratt Laboratory of Physical Chemistry at the University of Liverpool, and Sir Max was brought up in a scientific atmosphere He was one of the first of the great modern industrialists to receive a chemical education He was educated at Clifton College, and from there he went to Zurich, where he received the Swiss Government's diploma in applied chemistry

I have the most lively recollection of lunching with Sir Max Muspratt and Prof Donnan twenty seven years ago, on which occasion Sir Max expressed that extraordinary interest in science, an enthusiasm for research, which never left him

It is not too much to say that Sir Max Muspratt had a large part in bringing about the growth of the large research establishments in which Great Britain can justly pride itself In spite of the fact that his latter years were clouded by great personal misfortunes, he was always willing and anxious to discuss any scientific subject, not so much as regards its direct practical bearing, but in general terms His death is regretted by a far larger number of people than he would have imagined

F A FREETH

WE regret to announce the following deaths

Prof H G Chapman, director of cancer research in the University of Sydney, president of the Linnean Society of New South Wales in 1917-18, on May 25, aged fifty five years

Prof G C Comstock, emeritus director of the Washburn Observatory and professor of astronomy in the University of Wisconsin, on May 11, aged seventy nine years

Prof Otto J Kauffmann, emeritus professor of medicine in the University of Birmingham, on May 15, aged seventy one years

Prof J Y Simpson, professor of natural science in New College, Edinburgh, known for his work on the re interpretation of religion in the light of modern biology, on May 20, aged sixty years

News and Views

King's Birthday Honours

THE King's birthday honours list includes the names of the following men of science and others associated with scientific work and development *Baron* Sir Hugo Hirst, chairman and managing director of the General Electric Company, Ltd *G.B.E* Sir John Reith, Director General of the British Broadcasting Corporation *K.B.E* Dr F G Banting Dominion of Canada, discoverer of insulin *Knights* Major R G Archibald, director of the Wellcome Tropical Research Laboratories, Sudan, Mr A W Flux, honorary vice president (past president) of the Royal Statistical Society, Mr Albert Howard, lately agricultural adviser to the States in Central India and Rajputana, Dr W H Moberly, vice chancellor of the University of Manchester, Dr C E Saunders, lately Dominion cerealist, Dominion of Canada, discoverer of Marquis Ruby, Reward and Garnet Wheat, Prof G Elliot Smith, professor of anatomy in the University of London (University College) *C B* Dr R E Stradling, director of Building and Road Research, Department of Scientific and Industrial Research *C.M G* Mr A C Bagshawe, secretary of the Department of Agriculture and Lands, Southern Rhodesia, Prof R S Troup, director of the Imperial Forestry Institute and professor of forestry in the University of Oxford, for services to forestry in the Colonies *C.I.E* Mr F Canning, chief conservator of forests, United Provinces, Mr P E Aitchison, chief conservator of forests, Bombay Presidency; Mr W McRae, director and Imperial mycologist, Imperial Institute of Agricultural Research, Pusa *C.B.E* Dr W L Balls, chief botanist, Egyptian Ministry of Agriculture, Mr L St L Pendred, editor in-chief of the *Engineer*, Dr L J Spencer, keeper of minerals, British Museum (Natural History). *O.B.E* Dr S G Barker, for research services to the Empire Marketing Board, Mr A D Cotton keeper of the Herbarium and Library, Royal Botanic Gardens, Kew, Miss E H Ekins, principal of Studley Horticultural and Agricultural College for Women, Miss Annie Lorrain Smith, for contributions to mycology and lichenology, Dr C Raeburn assistant director of the Geological Survey Department, Nigeria *M B E* Mr F G Harcourt curator of the Botanical Gardens and Agricultural Superintendent, Dominica Leeward Islands, Mr J D Kennedy, sylviculturist, Nigeria *I.S O* Mr G E Greig, lately senior warden of mines, Federated Malay States

Johann Bauschinger, 1834–93

AMONG those to whom German industry and engineering owed much in the latter part of last century was Johann Bauschinger, who was born on June 11 a century ago He began life as a school teacher, but became very widely known for his work on the testing of materials One of a large family of an artisan, Bauschinger was born in Nuremberg and was educated at the Nuremberg Commercial School, and the Polytechnic He was enabled to proceed to the University of Munich and, after studying mathematics and physics at the age of twenty three years he secured a post as teacher in the Commercial School at Fürth, where he spent nine years He then taught for a time in the Realgymnasium of Munich, and in 1868 was appointed professor of mechanics and graphic statics in the Technical High School there, which henceforth was the scene of his activities By 1870, he was in possession of a mechanical laboratory where, said Unwin, "Engineering experiments were carried out with a thoroughness and delicate accuracy never previously equalled"

He designed a new form of testing machine and applied Gauss's method of reading by reflection in instruments for measuring deformation of bodies when strained, made tests of cement, mortar, timber, cast iron, wrought iron and steel, and for the railway authorities made investigations on defective axles, rails, etc Much of his work was inspired by the labours of his famous countryman August Wöhler (1819–1914) An important outcome of Bauschinger's labours was the formation in Germany of a society for exchanging views on investigations similar to his own, and thus led to the foundation of the International Association for Testing Materials In his own particular line, he was regarded by Unwin as "the prince of observers" He died at Munich on November 25, 1893

Preparations for New Ascents into the Stratosphere

The National Geographic Society, Washington, D C, is co-operating with the U S Army Air Corps and other donors in a new ascent to the stratosphere to be made this month According to the *National Geographic Magazine* of April, the balloon to be used will have a capacity of 3,000,000 cubic feet, and will be manned by Maj William E Kepner and Capt Albert W Stevens The balloon fabric is of cotton impregnated with rubber, and the spherical gondola, which is made of a magnesium aluminium alloy is 8 ft 4 in in diameter The total weight to be raised including balloon, gondola equipment and crew, is nearly eight tons It is estimated that when the balloon rises from the earth partly inflated, the top will be 295 ft from the ground, at its 'ceiling', the balloon will be a sphere 180 ft in diameter Hydrogen is to be used for inflating it The gas valve in the top of the balloon will be operated from the gondola by compressed air The programme of scientific work includes the collection of samples of the atmosphere of the stratosphere, determination of electric gradient, observations of cosmic rays and of ozone content and photography at great heights According to the Brussels correspondent of the *Times*, Dr Max Cosyns, who accompanied Prof Piccard on his second ascent to the stratosphere, has completed his preparations for a new ascent (Nature, Nov 25, 1933, p 812) The gondola of the Belgian balloon has been constructed of aluminium

New Paris Zoo

The lures of Paris are many Its latest is a new zoo at Vincennes which should be well worth seeing Hagenbeck, in Germany, was one of the first to abolish the old and hideous system of keeping birds and beasts in cages The Zoological Society of London, when Sir Peter Chalmers Mitchell took over the reins of government, followed suit, starting with the fine sea-lions pond, and the now famous Mappin Terraces These last seem to have inspired the director of the new Paris Gardens, Prof Urbain, and the architect, M Charles Letrosne, for the dominant feature of the Gardens, we are told, is a towering mass of reinforced concrete, 200 ft high, shaped and coloured to look like reddish brown rock, with ledges for sheep, goats, and antelopes The interior of this mass contains two large reservoirs for the storage of water to supply pools in various parts of the Gardens. In the London Mappin Terraces similar reservoirs supply the wonderful Aquarium—the finest in Europe Another noteworthy feature of the Paris Gardens is a great aviary giving the birds plenty of room for flying Occupying an area of about 23 acres, it would seem to be reminiscent of the Gardens of the Zoological Society in London and at Whipsnade, and there is no doubt they will be as much appreciated The new Gardens occupy the site of the Colonial Exhibition in the Bois de Vincennes They were opened on June 2 by the President of the Republic, M Lebrun

The Indian Earthquake of January 15, 1934

This great earthquake is being studied by officers of the Geological Survey of India Their investigations in the central area are expected to last for several weeks longer, and their results will be published by the Survey at an early date In the meantime, three papers of some interest have appeared Sir E Pascoe's lecture on Indian earthquakes and their causes is published by the Royal Society of Arts (*Journal*, 82, 577–594, 1934), and papers on the North Bihar earthquake by Dr M S Krishnan and Dr S K Banerji in *Current Science* (2, 323–326, 326–331, 1934) From the observations so far made, it seems, according to Dr Banerji, that the earthquake fault reaches from Motihari to Monghyr, a distance of about 135 miles There is probably also a second fault, branching from near the middle of the latter and running in the direction of Purnea. Most of the seismographs in India were thrown out of action by the shock, but good records were obtained, and are here reproduced, at Colaba (Bombay) and Agra From the great preponderance of the surface waves compared with the primary and secondary waves, Dr Banerji concludes that the focus was at a very slight depth below the surface All three writers agree in attributing the earthquake to a disturbance of the isostatic compensation

After-Shocks of the Bihar Earthquake

At the end of May, the after shocks of the Bihar earthquake of January 15 increased in frequency and strength The strongest, which occurred at about 1 A M on May 31, seems to have originated within the focus of the principal earthquake, for it caused alarm at Muzaffurpur, Patna and other places in its epicentral area So far as is known, there was no loss of life and no damage except that walls injured in January collapsed, while fissures that had become filled with dust reappeared Shocks were also felt about noon on the same day in Assam, the first of which is reported to have lasted two minutes and to have been felt in Calcutta

Element No 93

The Rome correspondent of the *Times* states, in a short communication published in the issue of June 5, that an article in the *Giornale d'Italia* which surveys recent work on induced radioactivity by Prof Enrico Fermi, of the Royal University, Rome, includes the announcement that Prof Fermi has produced a new element, of atomic number 93 The new element was found when uranium, atomic number 92, was bombarded with neutrons , it is radioactive, with a half period of about 13 minutes This announcement would appear to be a sequel to the experiments reported by Prof Fermi in NATURE of May 19, p 757, when he described the effects of bombarding various elements with a powerful stream of neutrons Uranium was not among the elements mentioned by Prof Fermi in his communication, but it would seem that he has now succeeded in obtaining an effect from it

Science and Psychical Research

EARLY this year (January 6, p 18) we referred to the proposed formation of a body to be called 'The International Institute for Psychical Research", and expressed the hope that the men of science who had allowed their names to appear on the circular announcing the new organisation would see that whatever investigations were undertaken were in accord with what science demands of such inquiries Apparently it has been difficult to secure these essential conditions, for Prof D F Fraser Harris, who was announced as the research officer of the Institute, informs us that he has resigned that position When he invited a number of scientific friends to serve on the Committee of the Institute, he was under the impression that a laboratory was to be provided, but he now finds this is not so, and that there is a lack of appreciation of what scientific investigation signifies It may be recalled that Prof Elliot Smith, who was advertised a short time ago as president of the Institute, resigned a few weeks ago on account of ill health We understand that most of the chief men of science whose names were advertised in the list of members of the Consultative Committee of the Institute have also resigned In connexion with the subject of psychical research, Prof Fraser Harris, referring to the article 'From a Correspondent" in NATURE of May 19, p 747, writes — There is one circumstance not mentioned by the author of the account of the experiments of MM Osty (1932) on 'the unknown powers' produced by Rudi Schneider It is the fact that, between the medium and the sitters on one hand and the recording apparatus on the other, there was interposed a sheet of muslin stretched on a wooden frame Clearly, the medium on one side of this partition, even with all his limbs free and surrounded by any number of accomplices could not have played any tricks with the apparatus on the far side of the partition (A photograph of this screen is on p 54 of *Revue Métapsychique* 1932 No I)"

Tornado at Concepcion

A BRIEF summary of damage and loss of life caused by a tornado on May 27 in the Chilean town of Concepcion, the chief port of entry to southern Chile, appeared in some evening papers on May 28, and in the *Times* of May 29 The storm was described as a "cyclone", but the note in the *Times* stated that the damage occurred in a strip 65 ft wide, and if that statement is correct, there can be no doubt that this was a tornado of the American pattern, and a vigorous example at that, seeing that trees were uprooted and buildings were wrecked as the storm swept across the town, moving apparently from east to west One account stated that a house was lifted off the ground and carried along for a distance of nearly 55 yards The incident is of especial scientific interest , if the 'dust devils' of desert regions and the maritime or lacustrine waterspouts' are included under the term tornado', there appears to be hardly any part of the world where this small intense rotary storm may not occasionally occur , they are not uncommon in the Mediterranean, and Concepcion lies in the corresponding southern latitude and has the same type of climate with maximum rainfall in the winter half of the year It is then that the westerly winds invade a region that fringes the trade wind belt during the summer The date of this particular storm corresponds with late November in the Mediterranean, and in both regions the late autumn is in general about the middle of the wettest quarter of the year, when the tornado might be expected to occur most often in coastal regions, even though the American tornado is more a phenomenon of the late spring and summer

Trevithick Centenary Commemoration

AT a meeting of the general committee of the Trevithick Centenary Commemoration, held on May 31 at the Institution of Civil Engineers and presided over by Sir Murdoch Macdonald, the report of the Executive Committee appointed in October 1932 to make arrangements for the commemoration was presented by Mr H W Dickinson, honorary secretary, and passed The report showed that about £500 had been subscribed, and that the committee had been able to carry through the plans laid down Memorial services were held in Westminster Abbey and Dartford Parish Church, a memorial lecture was delivered by Prof C E Inglis, and memorial tablets have been erected at Merthyr Tydfil to mark the site of Trevithick's experiment of 1804 and at University College, London, to mark the experiment with the locomotive *Catch-me who-can* in 1808 A sum of money had also been allocated to assist in the erection of a tablet at Trevithick's birthplace The work of the committee had been greatly assisted by the hospitality of the Institution of Civil Engineers and by the generosity of Messrs Babcock and Wilcox, Ltd , who had defrayed the cost of the publication of the memorial volume on Trevithick by Messrs Dickinson and Titley An interesting outcome of the celebration was that it had led the Institution of Civil Engineers to appoint a committee to make an annual visitation to Westminster Abbey to inspect the various memorials to engineers there

Expedition to the Canadian Arctic

AN expedition, organised by the Oxford University Exploration Club with the full support of the Royal Geographical Society and the Canadian Government, is sailing shortly for Ellesmere Land in the Canadian

Arctic, under the leadership of Dr Noel Humphreys The plans of the Expedition are to leave London in July in a sealer chartered from Norway and to winter in Ellesmere Land, next spring being devoted to an exploration of Northern Ellesmere Land The interior is unexplored and a geological survey of this country will be the chief scientific work undertaken The Expedition is financed partly by its members and partly by scientific societies and individual subscribers The greater part of the food supply has been obtained free owing to the generosity of a number of firms The Expedition will consist of five or six members, but a geologist is still urgently required Besides being physically fit and prepared to be away from England for a year, he should have had some field experience Communications referring to the Expedition should be addressed to Mr E A A Shackleton, Oxford University Ellesmere Land Expedition, 1934, Royal Geographical Society London S W 7

Archæological Exploration in Alaska

Dr Aleš Hrdlička, accompanied by a number of volunteer students left Washington on May 11 for a further season's work on Kodiak Island Alaska Several seasons have already been devoted by Smithsonian expeditions, of which Dr Hrdlička has been in charge, to the examination of sites on this island The results have shown that it was at one time thickly populated and was in all probability a stepping stone in the peopling of America by migrants from Asia The earliest inhabitants, whose skeletal remains have been found at the bottom of the accumulated debris, represent the earliest remains of man which have been found in the far north They are not, however, ancient in the geological sense In type they approach the physical characters of the Indians of California and the west coast The earliest immigrants introduced a high order of stone culture, and many of the objects found with them are unique They were succeeded by the Aleut, who were the inhabitants at the time of the coming of the Russians A remarkable feature in the culture of the older population is that it is not identical throughout A marked change takes place in the course of their period of occupation In the coming season, work will be confined to one large village, already partially explored The site will be subjected to intensive study in the hope of obtaining a decisive answer to some, at least, of the problems which have been raised in the investigations of previous years

International Eugenics Conference

The biennial conference of the International Federation of Eugenic Organisations will take place at Zurich on July 18–21 under the presidency of Prof Ernst Rüdin of Munich A programme has been arranged providing for the discussion of subjects of immediate interest in which eminent specialists have been invited to take part Addresses will be delivered by, among others, Prof Rüdin on 'Racial Psychiatry—a Scheme for Topographical Research in Europe", Dr Mjoer on Measurement of Psychological Faculty as shown in Musical Ability", and Prof Von Verschuer on "Researches in Twins" Dr Rudin will also explain the provisions of the recent German eugenics law, and it is hoped that one of the public health officers of the Reich will give an address on the questionnaire now used in Germany for assessing intelligence grade Among the subjects down for discussion are the assessment of feeble mindedness—to be held in a joint session of the Committee for Racial Psychiatry and Section B of the International Committee for the Standardisation of Human Measurement—mental measurement and its relation to diagnosis of temperamental type, aspects of the problems of differences between, and inheritance in, monozygotic and dizygotic twins, and the best methods of conducting a central clearing house for human heredity, this last named including the questions of the establishment of national bureaux, and the protection of authors whose material is published The work of the Standardisation Committee in Anthropometry will be continued at the International Congress of Anthropological Sciences to be held in London at the end of July

Prof Erwin Baur

Heft 17 18 of *Die Naturwissenschaften*, which appeared on April 27 is devoted to the memory of Erwin Baur, who died in December last A short general account by Dr Max Hartmann of his work and its significance in leading to a general appreciation of genetics in Germany is followed by a series of twelve articles written by colleagues of Baur whom he trained in the institute of which he was head outlining in more detail the results achieved by the institute for plant breeding which he founded at Muncheberg Five papers dealing with his theoretical work discuss respectively his investigations of mutation, linkage, specific crossing and self sterility in *Antirrhinum*, and his genetical work on *Pelargonium* and *Cleome* In seven other papers are considered the practical plant breeding results obtained with rye, wheat, barley sweet lupins fodder plants potatoes and grapes Further papers on the practical results will appear in later numbers of the same journal An obituary notice of Prof Baur appeared in Nature of February 17

Barter in Great Britain

In the United States the direct barter of goods and services has developed rapidly since 1931 as a practical method of alleviating unemployment and social distress So far, little appears to have been done in Great Britain along similar lines, possibly because social insurance is highly developed, whereas in the United States it is practically non-existent It is of interest therefore to note that, according to *Progress and the Scientific Worker*, experimental barter schemes have been inaugurated near Cheltenham and Petersfield The Cheltenham scheme was started under the leadership of Prof Scott of University College, Cardiff Four acres of land were purchased to be cultivated co-operatively by a group of men. They receive no remuneration for their work other than coupons signed by Prof. Scott according to the time spent on work. These coupons are equivalent in value to half a pound of potatoes, and can also be exchanged for knitted socks made by a member or for boot repairs undertaken by another member. Later on, it is hoped to extend the variety of goods and services obtainable for the coupons. At Petersfield the system is further developed and the work undertaken by various members includes cultivation of allotments, poultry farming, wood cutting, cobbling, carpentry and general repairs. To break up the land a tractor has been borrowed from a local firm. The commodities or services are exchanged among the members while surplus farm produce is sent to an occupation centre in exchange for surplus clothes made in the centre.

Gutta Percha, Balata and Caoutchouc

PROF. G. G. HENDERSON in delivering the twenty-sixth Bedson Lecture in Newcastle upon Tyne on May 18 outlined the work carried out in his laboratories on the subjects of gutta percha, balata and caoutchouc. The peculiar difficulties of the subject—which he advised research workers to avoid—are the lack of criteria of purity, complete absence of crystalline compounds, ready resinification at temperatures above 40° and attack by air. Oxidation experiments with hydrogen peroxide yielded alcoholic substances in each case, which when treated successively with acetic anhydride, further peroxide and aqueous barium hydroxide gave from each source, so far as could be determined, the same final alcoholic product. Hydrogenation with a palladium catalyst gave results in agreement with the general formulæ $(C_5H_8)_x \rightarrow (C_5H_{10})_x$ with the anticipated increase in stability. This is in agreement with the general conception of chains of isoprene units linked head to tail with loss of one double bond per unit. The hydrochlorides of these substances on treatment with metallic zinc gave, not the same dihydrides, but quite different substances with the original empirical formula but one unsaturated linkage to each two isoprene units, which may be due to cyclisation on loss of hydrogen chloride. Finally, the dibromo addition compounds condensed with phenols in the presence of anhydrous ferric chloride to yield coloured substances with the properties of indicators, one being very suitable for the titration of halides with silver nitrate.

Marine Electrification

SEVERAL important developments in connexion with marine electrification are described in the *G.E.C. Journal* of February. In the past, fishing trawlers have been illuminated by means of carbide lamps which, apart from their disadvantages from an illuminating point of view, introduce a serious fire risk. Special equipment has now been designed and installed on one of the trawlers of a Scottish fishing fleet which enables electric lighting to be used. The installation has been very successful and the practice of electrically floodlighting the decks of trawlers will be widely used. The Company also completed the electrical propulsion equipment of the Diesel-electric tug, *Acklam Cross*. This is the first British vessel of her type, the first to have high speed Diesel prime movers, the first to have a clear after deck, and the first to have an electrical system of starting the prime movers. The system adopted seems admirably suited to fulfil all the special requirements of a tug. It is capable of going on duty at a moment's notice. It is also capable of rapid manœuvring when towing large vessels in and out of congested harbours. There is practically no delay in exerting full power ahead or astern. The Diesel-electric engine can be started up as quickly as a motor car engine and during periods of inactivity no fuel at all is consumed. The control of the speed and the direction of the controller is directly in the hands of the navigating officer. Starting is effected immediately by pressing a button. The mean speed over the measured mile was 11.15 knots. The time taken from rest to full speed ahead was 24 seconds and from stop to full astern was 16 seconds. The electro-hydraulic steering gear was very efficient, the vessel being capable of turning at full speed in under two lengths.

Research Activities of the Mellon Institute

THE twenty-first annual report of the Director of the Mellon Institute, covering the year 1933–34, directs attention to the improvement in the position of research during recent months and illustrates the wide range of industries which benefit from the activities of the Institute. Sixty-six industrial fellowships were in operation during the year requiring the services of 101 fellows and 34 assistants, and fifty-five fellowships were in operation at the end of the year. Fellows and assistants then numbered 104 as against 98 in the previous year; new fellowships commencing operations during the year dealt with cosmetics, nitrogen compounds, calgonising, rayon, new plastics, phosphates, tar acids, textile finishing, etc. The calgonising fellowship is concerned with the properties and utility of sodium metaphosphate ('calgon') in textile and laundry technology, the fellowship on phosphates is occupied with their pharmacology and therapeutic value, and a fellowship to investigate problems in starch technology has recently been accepted. The discovery of a process for flaking coffee by the application of high pressure to ground freshly roasted coffee made in a study of the packing of coffee is claimed as an important technical and practical advance. Other investigations have led to the marketing of new and improved strained foods. Industrial applications of the newer organic solvents have been assisted and a new water-soluble lubricant has been introduced for worsteds and wool. New plasticisers, new types of resins, adhesives which do not cause discoloration of envelopes on sealing, the synthesis of new types of amines, are among other achievements of the Institute, which can also point to important investigations on steel, the development of novel building materials, studies on heat insulation and efforts at smoke abatement as other evidence of its importance to the general welfare The fellows of the pure chemistry department have completed a number of important investigations on quinine, the cinchona alkaloids, etc , while the Institute has also supported investigations on pneumonia and pulmonary diseases at the Western Pennsylvania Hospital

Aquarist and Pond Keeper

THE sixth volume of the *Aquarist and Pond Keeper*, which opens with the March–April issue, has a change of cover, a new headpiece and other improvements in printing and illustrations The magazine keeps up its character in every way, and is full of information for those who are fond of aquaria, vivaria and pond culture The articles in the present number include the first of a new series by Arthur Denham on the keeping, breeding and rearing of tropical fishes, and aquarium notes by E G Boulenger, director of the Zoological Society s aquarium, and by S W Weller, curator of the Brighton Aquarium An angler fish or 'fishing frog' more than three feet in length, said to be the finest specimen of its kind ever exhibited alive, has been acquired for the Brighton Aquarium It will be interesting to see how long it lives, for this species is notoriously difficult to keep in confinement, especially those of such a large size

The Merseyside Aquarium Society

ONE of the most extensive collections of British fresh water aquaria and aquatic and river side vegetation, in addition to foreign aquaria, has lately been brought together by the Merseyside Aquarium Society at its aquarium at Cliff House, Wallasey which was opened by the Mayor of Wallasey in March 1932 The collection, which now comprises some sixty tanks, is claimed to be the most extensive of its kind in the North of England and situated in extensive glass houses, is largely the result of much hard work by enthusiasts in all classes of life in an effort to establish a really efficient scientific and public aquarium on Merseyside The Merseyside Aquarium Society was instituted in 1926, largely through the efforts of Mr F Jefferies, a past president of the Liverpool Naturalists' Field Club, and incorporated in 1930, and its first president was the late Prof James Johnstone The president of the Society is Alderman A H Evans of Wallasey, the vice-presidents Prof J H Orton, professor of zoology in the University of Liverpool, W S Laverock, lately of the Liverpool Museums, and Alderman D R Charlesworth, ex mayor of Wallasey, and the honorary secretary, Mr F Jefferies By a system of exchange, the Cliff Aquarium has acquired a number of valuable exhibits from the New York Aquarium Society, and it has lately been successful in breeding and rearing the axolotl (*Amblystoma*) to maturity The present premises have been loaned the Society by the Wallasey Corporation, but the Aquarium is only considered a nucleus for a much larger building which it is hoped to have built as a municipal affair in the future. The Society issues a volume of *Proceedings*, holds six indoor meetings annually, and affords special help for the amateur aquarists, for the exchange of knowledge and experience amongst experts, and to promote school aquaria and vivaria

Advances in Oceanographical Research

THE great and growing importance of fundamental research in marine biology and oceanography has recently been emphasised by the launch of two new vessels specially ordered and designed for this work On September 23, 1933, a new French research vessel, the *Président Théodore Tissier*, left the builder's yard This ship, built to the order of L'Office Scientifique et Technique des Pêches Maritimes de France, is approximately 160 ft in length, fitted with up to-date Diesel engines capable of producing a maximum speed of 11 knots, and fully equipped with all the latest apparatus for both oceanographical and biological researches The *Président-Théodore-Tissier* has now completed her trials and is already in commission A few months before the launch of the French vessel, the Danish Biological Station, Copenhagen, took over from the builders the new research ship *Biologen* (Report of the Danish Biological Station to the Ministry of Shipping and Fisheries, 38, 1933 Copenhagen C A Reitzel) Though considerably smaller than the *Président-Théodore Tissier*, the Danish vessel is also fully equipped for carrying out scientific work in both narrow and high seas In view of the acquisition of these two highly efficient modern research vessels by foreign powers, it is all the more regrettable that H M S *Challenger*, originally destined for similar work by Great Britain, should have had to be given over to other purposes, and the activities of our existing ships seriously curtailed

A Potato Research Station

THE establishment of such a station in one of the important potato growing districts is advocated by Sir John Russell in the foreword to the report of the sixteenth Rothamsted Conference upon Problems of Potato Growing" (Harpenden Rothamsted Experimental Station 2*s*) Sir John concludes that economical production of potatoes necessitates the use of good seed of the most suitable varieties, appropriate schemes of manuring and cultivation, control of insect and fungus pests and of other agencies causing disease and methods for dealing with excess produce All these topics are dealt with by expert contributors in this report The fields of research developed around this homely plant, notably the virus disease problems, show how technical and specialised are the problems raised by this crop, and though the present research and advisory system deals very effectively with them to a point, Sir John concludes that there is room for such a special research station continuously concerned with investigations into the physiology of the potato and the utilisation of the tuber

Research Regulations in Germany

THE April number of the *Fight Against Disease*, the quarterly journal of the Research Defence Society, among other matter, gives extracts from the new German law controlling vivisection, which show that the German regulations governing experiments on living animals are substantially the same as those which have been enforced by the Home Secretary in Great Britain for more than half a century

National Baby Week Council

THE annual report of this Council, recently issued, describes the work accomplished during 1933 and constitutes another record of increased activity and influence A tribute is paid to the co-operation of the Press and of shops and stores in propaganda respecting maternity and child welfare problems It is suggested that propaganda should this year be devoted to the subject of The Making of an A 1 Nation", and National Baby Week' is to be celebrated on July 1–7 The Council has suffered from the financial stringency, but by exercising the strictest economy, income for the year exceeded expenditure by the small margin of about £12

South-Eastern Union of Scientific Societies

THE thirty ninth Annual Congress of the South Eastern Union of Scientific Societies will be held at the University of Reading on July 11–14 under the presidency of Prof H L Hawkins, professor of geology in the University On July 11, Prof Hawkins will deliver his presidential address entitled Fossils and Men" The presidents of sections will deliver the following addresses during the Congress T D Kendrick (Archæology), The Art and Archæology of the Early Anglo Saxons', Dr Macgregor Skene (Botany), Some Problems of Germination", Dr C B Williams (Zoology), Insect Immigration in Great Britain', T H Edmunds (Geology), "The Water Supply and Geology of the South East of England, C H Grinling (Regional Survey), Surrey for Action" On July 13, at 8 p m, Prof E B Poulton will deliver a public lecture entitled The Power of Changing Colour as a Form of Protective Resemblance" Further information can be obtained from the Hon General Secretary, 14, High View Close, Norwood, S E 19

American Academy of Arts and Sciences

AT the annual meeting of the American Academy of Arts and Sciences held on May 9, the following officers were elected for 1934–35 *President*, Prof G H Parker, *Corresponding Secretary*, Prof Tenney L Davis, *Recording Secretary*, W E Clark, *Treasurer*, I Bowditch, *Librarian*, Prof Alfred C Lane, *Editor*, Prof Robert P Bigelow, *Foreign Honorary Members*, Prof R A Fisher, Galton professor of eugenics in University College, London; Prof A V Hill, Foulerton Research professor of the Royal Society, and University professor of physiology in University College, London, Prof Arthur H Holmes, professor of geology in the University of Durham, Prof Paul Janet, professor of electrotechnics in the Sorbonne, Paris, Prof Luigi Lombardi, Rome, and Prof R Willstätter, Munich

Announcements

PROF A V HILL will open a discussion at the Royal Society on June 14 on "Methods of Measuring and Factors Determining the Speed of Chemical Reaction"

THE RIGHT HON WALTER E ELLIOT, Minister of Agriculture and Fisheries, will inspect the field plots and laboratories of the Rothamsted Experimental Station on June 20, at 11 15 a.m On the same day, Mr Elliot will present to the Trustees the deeds of the land newly acquired as a result of the recent public appeal

PROF J B CONANT, president of Harvard University, formerly professor of chemistry in the University, has been awarded the medal of the American Institute of Chemists The award is made in recognition of 'outstanding service to the science of chemistry and the profession of chemists in America Prof Conant is well known for his work on reduction and oxidation in organic chemistry, and on hæmoglobin and chlorophyll

WE have received the second supplement, 1931–1933, to the Catalogue of Lewis's Medical and Scientific Lending Library' (London Lewis's Library, 136, Gower Street, London, W C 1 2*s* net) Works are listed alphabetically under authors' names, and at the end there is a classified index of subjects, under each of which authors' names are given, and the full title of the works will be found on reference to the body of the catalogue All the sciences appear to be represented, and the list contains nearly 3,000 titles

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —An assistant lecturer in physics in King's College, London —The Secretary (June 12) A veterinary officer to the Berkshire County Council—The Clerk, Shire Hall, Reading (June 19) Assistant lecturers in geology and geography chemistry, and physics at University College, Swansea—The Registrar (June 20) A superintendent of parks in the Borough of Barking—The Town Clerk, Town Hall, Barking (June 20) A lecturer (woman) in geography at Norwich Training College—The Principal (June 20) An inspector of agriculture in the Department of Agriculture and Forests, Sudan Government—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, London, S W 1 (June 21) A lecturer in pure and applied technology at Leicester College of Technology—The Director of Education (June 22) An assistant in the Department of Natural Philosophy in the University of St Andrews—The Secretary (June 23) A senior lecturer in mathematics at the Huguenot University College, Wellington, Cape Province, South Africa—The Registrar (Aug 14) Evening teachers of pure and applied mathematics, economics, economic geography, etc, at the Wandsworth Technical Institute, London, S W 18—The Secretary

Activities of Life and the Second Law of Thermodynamics

WE regret the necessity of prolonging this discussion but in spite of the letter of Sir James Jeans[1] we persist in the conviction that it is his reasoning not ours which is fallacious We are quite aware that the change of positional entropy associated with the type of process which he cites involves the factor Nk where k is the Boltzmann constant and N the number of particles concerned in the process nor do we dispute the correctness of the well known formulæ which he quotes We must however point out that he is wrong in assuming that the number of particles *must* coincide with the number of molecules We might ask why not the number of atoms or the number of protons and electrons ? The answer is that for a given process of redistribution the particles are those units whose relationship to one another is altered but whose internal structure remains unaffected In the process of sorting out trucks each truck is to be reckoned as a particle in the process of steering the *Mauretania* the ship is a particle

To revert to the type of case originally considered by Sir James Jeans let us imagine a large number of equal spheres of glass on a frictionless horizontal plane If N of these spheres be moved from a place where the (superficial) density of distribution of the spheres is v to a place of higher density v^1 then the decrease of positional entropy of the system is equal to kN $(\log v^1 - \log v)$ According to Sir James Jeans however the decrease of positional entropy would be kn_1N $(\log v^1 - \log v)$ where n_1 is the number of molecules contained in each sphere If he reasons in this manner we would ask him why the decrease of positional entropy should not also be kn_2N $(\log v^1 - \log v)$ where n_2 is the number of atoms or the number of protons and electrons contained in each sphere This paradox clearly reveals the fallacy in his reasoning

Finally we would point out that the total entropy of an assembly of N identical systems each made up of n ultimate particles may be resolved into the sum of two terms the first of the order Nk determined by the configuration (and relative motion) of the centres of mass of the N systems the second of the order $N(n - 1)k$ determined by the internal arrangement of the ultimate particles in each system In any process in which the internal arrangement of the systems remains unchanged only the *first* term in the entropy is affected We think it scarcely possible that Sir James Jeans would dispute this statement although the views expressed in his last letter contradict it

Calcium Isotopes and the Problem of Potassium

BY the systematic use of the purest materials, I have succeeded in reducing the effect of potassium in the mass spectrum of calcium to a negligible quantity Under these conditions the line 41 disappears completely and it is quite safe to conclude that the isotope Ca 41 does not exist at least to 1 part in 1000 in the element Photometry gives the following provisional constitution for calcium

Mass numbers	40	42	43	44
Abundance	97	0 8	0 2	2 3

It will be noted that the abundance of Ca 44 is much greater than that originally reported by Dempster[1] and is in better accord with the chemical atomic weight

I have been kindly supplied with compounds of calcium extracted from biotite by Prof G v Hevesy and from pegmatites from Rhiconich and Portsoy by Prof J Kendall On the view that the radioactivity of potassium is due to the simple beta ray transformation of K 41 to Ca 41 these samples should be rich in the latter On analysis their mass spectra showed no appreciable difference from that of ordinary calcium so that the abnormal atomic weights reported by Kendall[2] cannot be ascribed to the presence of the hypothetical isotope 41

Hevesy s beautiful distillation experiments have shown that the radioactivity of potassium is unlikely to be associated with the abundant light isotope 39 so that the failure to detect Ca 41 appears to favour some more complex theory of the disintegration such as that recently suggested by Gamow[3]

Interaction of Radio Waves

IN our letter published in NATURE of February 10 last Dr Martyn and I stated that we had found that Tellegen s observation of an apparent interaction of radio waves could be explained by taking account of the changes in the mean velocity of agitation of electrons in the ionosphere produced by a strong electric wave

Another interesting consequence of this effect due to an electric wave may be pointed out namely the production of so called atmospherics in a radio receiver by modulation of the received carrier wave

An atmospheric electric pulse acting on the electrons in a part of the ionosphere through which the carrier wave passes momentarily increases the absorbing power of that part and so momentarily reduces the amplitude of the received carrier wave Thus an irregular succession of sounds is produced in the receiver similar to the effects produced more directly by atmospheric pulses

Thus it appears possible that observed atmospherics are of two types one associated with and proportional to the intensity of the carrier wave and the other completely independent of the carrier wave

Pseudorca crassidens (Owen) on the Glamorgan Coast

DURING the night of Sunday, May 6, a school of cetaceans was stranded at Whiteford Sands, Llanmadog, on the Gower coast of Glamorgan We visited the spot as soon as possible and found twenty one specimens, which we identified as False Killers, *Pseudorca crassidens* (Owen) Mr M A C Hinton, who has examined one of the skulls, agrees with the identification It was possible to make a more or less detailed examination of these and to procure some material for this Museum, another specimen, which was not reported to us until later, was some distance away and we did not have an opportunity of examining it

[*Photo Western Mail and Echo, Ltd.*

FIG 1. False killer dolphins stranded on Glamorgan coast on May 6, 1934.

It will be remembered that this dolphin was by many considered to be one of the rarest of cetaceans, "on the verge of extinction", until October 1927, when a school of about 130 was stranded in the Dornoch Firth In December 1928 a still larger school was reported from the South African coast, near Cape Town, and another school from Velanai Island, near Kayts, in Ceylon, in August 1929 Sir Sidney Harmer, in a letter to these columns[1], gave a summary of occurrences of this species and suggested that its supposed rarity was due to its being an inhabitant of the open seas and thus seldom observed in the neighbourhood of land

A certain amount of data of biological interest has been obtained about the Llanmadog specimens, and it is hoped to publish this in due course

Meteorology and Gliding

IN a letter to NATURE of May 5, Mr G E Collins asks whether a sensitive thermometer would be useful on a sailplane for detecting rising air, and desires indications as to how sailplane pilots can assist the science of meteorology

To make satisfactory measurements of temperature and humidity inside and outside clouds by carrying a meteorograph on an aeroplane is difficult, because the instruments at present made are not nearly rapid enough in their responses to record features lasting about a second, and in Germany they have developed a scheme whereby the more slowly moving sailplane carries the self recording apparatus and is towed by an aeroplane to the region where observations are required, because the demands for rapidity in the meteorograph will then be less severe

In the absence of a special institution devoted to these purposes, measurements of the variations of temperature and humidity are difficult, but information of value to the gliding movement as well as to meteorology could be got by systematic measurements, or careful estimates, of the vertical air movements in the neighbourhood of clouds of the different types, especially if the type were defined by the use of a camera Thus on March 18, the day when Mr Miles, Mr Collins and Mr Humphries all made long flights, some of the verbal descriptions that I heard indicated line squalls, but the photographs and the account given in the *Sailplane and Glider* of April show, I think conclusively, that the clouds belonged in general either to the type that has been classed as 'longitudinal' or to the rectangular' type The photograph on p 52 of that issue, which illustrates the 'streets of clouds' utilised by the pilots shows very clearly the spiral form that is characteristic of longitudinal cells it suggests also that the maximum lift would not be immediately under the axis of the spiral

My impression, derived solely from theoretical considerations, is that under such clouds the up currents would not usually be strong, but the formation of soft hail and the shapes in the photographs indicate that on that day the ascent was fairly rapid—in fact, some at least of the clouds were approximating to cumulo nimbus It will be interesting to see whether the development of convection in these types is stronger in summer than in spring

Molecular Weights of Celluloses

DURING recent years a good deal of attention has been given to the investigation of the molecular weight of 'native' cellulose, but the results are highly discordant, the values most frequently quoted being those of Mark[1] (about 30,000, on the basis of micell length by X-ray analysis and other data), Stamm[2] (40,000, by sedimentation equilibrium in the ultracentrifuge) and Staudinger[3] (about 120,000 by extrapolation of viscosity vs molecular weight data) The sedimentation equilibrium method is the soundest theoretically, and we have recently demonstrated experimentally[4] that it gives correct molecular weight values for long-chain molecules which, like cellulose, give highly viscous solutions.

In continuation of Stamm s work we have determined the molecular weights (by sedimentation equilibrium in the Svedberg ultracentrifuge) and we find that the specific viscosity increases for a number of celluloses and regenerated celluloses dissolved in cuprammonium solvent Calculating the results in the same manner as Stamm did we obtain apparent molecular weights of the cellulose copper complex ranging from 100 000 to 300 000 depending upon the extent to which degradation had occurred during the previous history of the specimens The 300 000 value was obtained for a portion of cellulose which Stamm studied and for which he reported a value of 55 000 for the cellulose-copper complex We suspect that degradation inadvertently occurred during Stamm s determinations To obtain the molecular weight on a copper free basis Stamm assumed one copper atom combined per glucose group corresponding to a correction factor of 72 per cent and leading to his final value of 40 000 Our results on combined copper and also consideration of the partial specific volume of the copper compound yield a correction factor of 60 per cent so that our cellulose molecular weights range from 60 000 to 180 000 We estimate the molecular weight of native cellulose to be in the neighbourhood of 300 000

The specific viscosity of the cuprammonium solutions of the celluloses increases in a definite manner with the molecular weight so that after empirical calibration of the relationship by ultracentrifugal analysis it is possible to calculate average molecular weights from viscosity data The numerical relationship in the range of molecular weight that we have studied varies appreciably with the composition of the solvent and is not in agreement with the relationship published by Staudinger The application of Staudinger s equation to our viscosity data gives molecular weight values of 20 000 to 90 000 that is from a third to a half as great as the ultracentrifuge values

Natural Interconversion of Isomeric Sugars

THE mechanism involved in the smooth transformation of one simple sugar into another is a matter of the utmost importance to the chemist and the physiologist alike but little light was thrown upon the subject until Robinson[1] introduced the interesting theory that Walden inversion (conditioned by the enzymatic hydrolysis of phosphoric esters) within the sugar molecule is an agency for such changes This hypothesis presents a simple and rational explanation of the conversion of glucose into galactose by the mammary glands during lactation and lends colour to the suggestion that the primary constituent of nucleic acid is the commonly-occurring xylose which undergoes conversion to ribose in an analogous manner. Mathers and Robertson[2] in a research on the hydrolysis of *p* toluenesulphonyl esters of glucose recently adduced evidence which strongly supported this view in as much as they were able to convert a derivative of glucose into a derivative of altrose in one operation Cognate researches have brought to light the following significant facts

The alkaline hydrolysis of

(1) 2 3 Di *p* toluenesulphonyl 4 6 dimethyl α methylglucoside yields a 2 3-anhydro 4 6 dimethyl α methylhexoside and 4 6-dimethyl α methylaltroside[2]

(2) 2 3 Di-*p* toluenesulphonyl 4 6 benzylidene α methylglucoside yields a 2 3 anhydro 4 6 benzylidene α methylhexoside and a monomethyl 4 : 6 benzylidine α methylhexoside which is not a derivative of glucose or mannose

(3) 2 3 Dimethyl 4 6-di-*p* toluenesulphonyl α methylglucoside yields a complicated mixture containing a derivative of glucoseen

(4) 3 *p* Toluenesulphonyl diacetone glucose gives a quantitative yield of diacetone glucose

(5) 2 3 Dimethyl 4-*p* toluenesulphonyl 6 triphenylmethyl α methylglucoside gives an almost quantitative yield of 2 3 dimethyl 6 triphenylmethyl α methylglucoside

(6) 2 3 6 Trimethyl 4-*p* toluenesulphonyl β methylglucoside gives unchanged material and 2 3 6 trimethyl β methylglucoside

Viewing the results as a whole it is evident that these hydrolytic reactions fall into two main groups which may be characterised as normal and abnormal according as the original substance contains one or two *p* toluenesulphonyl residues in neighbouring positions It is also worthy of note that in the cases where Walden inversion has been proved to occur such inversion is accompanied by anhydro formation This fact at once suggests the idea that anhydro formation may be a necessary precursor to this type of inversion which follows as a consequence of the opening of the anhydro ring Such a hypothesis is in keeping with the main principle of the Robinson conception and at the same time invalidates the criticism levelled against it by Levene[3] whose evidence is based upon the hydrolysis of a phosphoric ester of 5 methyl monacetone xylose in which the possibility of anhydro formation is precluded

A full account of these investigations will be published later and it is hoped that the various extensions of the work which are now on hand will lead to a definite elucidation of this complicated but highly important problem

A New Type of Artificial β Radioactivity

THE energy spectrum of positive electrons from magnesium when bombarded by α particles of radium C reduced in range to 6 3 cm were investigated by a method already described[1] It was found that the number of positives is less than that expected from the measurements of the integral effect Changing the direction of the magnetic field, a great number of negative electrons could be observed The number of negative electrons was about four times as great as the number of positive electrons.

In order to ascertain the true origin of the negative electrons, the following experiments were performed A sheet of tinfoil or paper was exposed to α rays under the same conditions as the magnesium The absence of radioactive impurities was proved by the absence of β particles in these two cases The β particles were also absent when the source was covered by a tinfoil in order to stop the α particles Thus it is evident that the phenomenon is due to the bombardment of α particles

The number of negative electrons quickly diminishes with time (the half period is about 3 min) The limit of the continuous spectrum of the negative electrons is above 2×10^6 e v The probable nuclear reactions in the case of positive and negative electrons may be written in the following way

$$ {}_{12}Mg^{24} + {}_{2}He^{4} \rightarrow {}_{14}Si^{27} + {}_{0}n^{1}, \quad {}_{14}Si^{27} \rightarrow {}_{13}Al^{27} + \epsilon+ $$

(Curie Joliot reaction)

for positives and

$$ (1) \quad {}_{12}Mg^{25} + {}_{2}He^{4} \rightarrow {}_{13}Al^{28} + {}_{1}H^{1}, \quad {}_{13}Al^{28} \rightarrow {}_{14}Si^{28} + \epsilon- $$

or

$$ (2) \quad {}_{12}Mg^{26} + {}_{2}He^{4} \rightarrow {}_{13}Al^{29} + {}_{1}H^{1}, \quad {}_{13}Al^{29} \rightarrow {}_{14}Si^{29} + \epsilon- $$

for negatives In both cases we ought to detect radioactive atoms of aluminium

In the case of aluminium we were also able to obtain the emission of negative electrons, but their number is considerably less than the number of positive electrons

Absorption of Hydrogen by Nickel

IN order to measure the adsorption of hydrogen by pure nickel, free from oxygen, I used a silica tube, containing 12 kilometres of a very thin nickel wire (total weight of the wire 42 grams, mean diameter 0 022 mm) giving an available surface of at least 8,400 cm^2 The preliminary results indicate that between 200° and 650° C , and pressures up to 0 2 mm Hg, there is no measurable adsorption of hydrogen, but an appreciable absorption (homogeneous solution) The results are in good agreement with Sieverts' measurements with much thicker nickel wire at higher pressures and temperatures[1] The amount of absorbed hydrogen at a constant temperature is, within the experimental error, proportional to the square root of the pressure, and increases at constant pressure with increasing temperature, obeying the simple equation $\log a = A - B/T$. The heat of absorption, calculated from this isobare, is a little less than -3 k cal per gram mol hydrogen

Further details, together with the results at lower temperatures, which are under investigation, will be published shortly

Production of Large Quantities of Heavy Water

FROM the discussion recently held in the Royal Society[1], and from several communications on heavy hydrogen published in NATURE, it is obvious that larger quantities of heavy water are at present much needed for investigations in several branches of physics, chemistry and biology To meet this demand, Imperial Chemical Industries, Ltd , is to undertake commercial production at Billingham[2] It may also be of interest to report in this connexion, that various concentrates of the new water are now produced on a large scale in Norway by Norsk Hydro Elektrisk Kvælstofaktieselskab, Oslo Large quantities of '1 300 water' can be obtained from the above company, and richer concentrates will be available at a later date

This company at its works in Rjukan has one of the largest electrolytic hydrogen plants of the world, with a capacity of about 20,000 m^3 per hour Assuming the efficiency of separation by electrolysis so low as 10 per cent[3], a quantity of about 10 litres of pure' heavy water a day can be produced if the consumption requires

In full agreement with other investigators, it has been found that the efficiency is only slightly affected by the conditions of the electrolysis[1,4] However, certain difficulties arose using sulphuric acid with lead electrodes, due to the formation of porous lead on the cathodes and to the formation of fog The efficiency of separation in both acid and alkaline solution agree fairly well with that found, for example, by Harteck[5] Further details of the experimental results are to be published shortly in the *Zeitschrift für Elektrochemie*

Galvanometer Amplification by Photo-Cell

I NOTE with interest Prof A V Hill's letter in NATURE of May 5, describing the use of a Weston photronic' cell in a differential galvanometer relay It is somewhat surprising that Prof Hill's apparatus gives such a small amplification A Weston cell which has been used in a photo relay in this Laboratory for the last three months has given consistently a current amplification of 200 As we are using the same type of galvanometer as Prof Hill, it would seem that the only reason which can explain his having not obtained more than a twenty fold amplification must be the difference in the optical system

Full details will be found in a Laboratory Note communicated to the *Journal of Scientific Instruments* early in March

A Simple Modification of Morse s Rule

MORSE[1] introduced an empirical rule to the effect that

$$\omega_e r_e^3 \approx 3 \times 10^{-21}\ \text{cm}^2 \qquad (1)$$

where ω_e, r_e, respectively, are the equilibrium nuclear vibration frequency (in cm^{-1}) and the equilibrium nuclear separation (in cm) of a diatomic molecule, as deduced from spectra In a recent paper[2], dealing with the classification of non hydride diatomic molecules into groups and periods I have emphasised the importance of the group number n equal to the number of shared electrons or total number of valency electrons of the two separate atoms The way in which the errors from the strict requirements of Morse s rule distribute themselves in certain periods suggests that the insertion of some function of the group number into the Morse expression might lead to better agreement with observation For non hydride diatomic molecules of the period containing two completed K rings associated with each nucleus I have derived the following empirical modification of Morse s relationship

$$\omega_e r_e^3 \sqrt{n} = 9\ 55 \quad 10^{-21}\ \text{cm}^2 \qquad (2)$$

The mean error in deduction of r_e from ω_e values for 29 test cases of electronic levels of diatomic molecules of the specified kind amounts to ± 1 3 per cent from experimental values whilst the mean error using the unmodified Morse expression for the same cases is ± 5 2 per cent The results will be communicated in due course in another place

Inheritance in Fresh-water Ostracods

PROF MACBRIDE s recent article in NATURE[1] on Inheritance of Acquired Habits leads me to direct attention to some interesting information which is available from the study of fresh water ostracods

Fresh water ostracods possess both relatively and absolutely the largest sperms known throughout the animal kingdom while quite recently it has been discovered that these enormous sperms are highly motile The sperms are passed into the spermatheca of the female which possesses a spermathecal duct highly complicated in structure and also exceptionally long Under the proper conditions, the large sperms can be seen moving very actively both in the spermatheca and also in the upper or proximal region of the duct The fresh water ostracods are also remarkable for the wide prevalence of parthenogenesis In some cases, whole genera exist in which males are unknown One of the best known genera in this connexion is that of *Herpetocypris* containing the well known species *H reptans* which abounds practically in every pond in the British Isles and is distributed throughout Europe

The genus is a well-defined one, and two years ago taking the genus as described by Sars in Crustacea of Norway" (vol 9), I estimated that there were some twelve species occurring throughout the world, and in no case were the males known The most remarkable fact remains however, that the spermatheca and in particular the spermathecal duct, remains in *H reptans* and in all other species examined nor does it show the slightest sign of degeneration It is not proposed to give here further taxonomic details but anyone familiar with the taxonomy of fresh water ostracods will know many parallel instances

It is fairly obvious that at one time the males must have existed in each species of *Herpetocypris*, and since the males have disappeared entirely from the genus exclusive parthenogenetic reproduction must have been going on for a considerable length of time most probably for thousands if not millions of generations yet this useless spermathecal duct remains

If we treat the matter from a genetical point of view there is a fairly simple explanation but it seems to me extremely difficult to account for the persistence of this highly complicated genital organ if we accept the theory of the Inheritance of Acquired Habit Moreover the case becomes all the more striking when we consider other groups of animals in which parthenogenesis occurs For here it is almost universally true that individuals reproducing solely by parthenogenesis usually have their genital organs impaired in some way

A G LOWNDES

Marlborough College

[1] NATURE 133 598 April 21 1934

MR LOWNDES has misunderstood my article Its purpose was not to put forward a *theory* of the heritability of acquired habit but to show that this heritability has been experimentally *proved to be a fact* If this is so it is possible to explain all cases where the course of evolution has been followed in detail as well as to explain the recapitulatory element in development

Parasitism in Heavy Water of Low Concentration

THE first biological experiments[1] with heavy water (May 1933) showed that a low concentration of diplogen (1 part in 2 000) may have a beneficial effect on forms such as *Spirogyra* (the average longevity of 355 cells in filament sections of 10 50 cells in the diplogen water was 7 6 days, and the average for 322 cells in ordinary water was 1 6 days) It was also reported[2] that cell division in *Euglena* is increased in this dilute heavy water (density 1 00006) Meyer[3] confirmed the dilute heavy water effect by demonstrating that mats of *Aspergillus* showed sixteen times the dry weight of controls

We have found that flatworms (*Planaria maculata* and *Phagocata gracilis*) kept in dilute heavy water *for long periods show a striking difference* in the rate of shrinkage in body size After four months, the animals in ordinary water were only one fifth the length of the specimens in the diplogen water This was probably due to reduced enzymic hydrolysis in the starving animals since we have shown[4] that the dilute heavy water reduces the activity of amylase and zymin (the enzyme and substrate were incubated separately in the water and no effect was obtained if the substrate only was incubated or if both were allowed to react immediately) The experiment was repeated in more concentrated heavy water (1 213 diplogen ratio) and a new effect appeared The *Planaria* in heavy water of this concentration were rapidly parasitised by moulds and succumbed within three weeks (Fig 1) In some cases the living animal becomes invested with slime mould and in others is covered with tufts of mycelium The reduced metabolism and movement are possible factors in addition to the specific effect of this concentration of diplogen on mould growth

A similar increase in the growth of moulds was seen in tests of *Aquilegia* seeds kindly supplied by the Cambridge Seed Testing Station through the courtesy of Mr Hugh Richardson of Wheelbirks Northumberland In the 0 47 per cent diplogen cultures masses of white mould mycelium appeared (Fig 1) but these were chiefly saprophytic since they occurred mostly on the unsprouted seeds

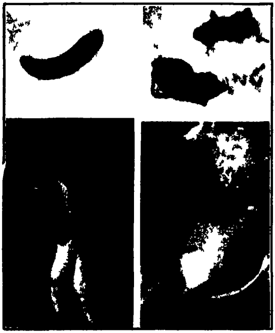

Fig 1 Upper left a control planarian in ordinary water Upper right two representative planarians killed by mould in 0 47 per cent heavy water Lower left sprouting *Aquilegia* seeds in ordinary water Lower right seedling in 0 47 per cent heavy water surrounded by white mould

It would appear from the work of Meyer on *Aspergillus* and the experiments reported in this note that diplogen in 1 200 concentrations has a specific effect in stimulating the growth of moulds and possibly bacteria This property should afford many interesting problems in parasitology and might be of considerable importance in the possible therapeutic use of dilute heavy water

Physiology of Deep Diving in the Whale

Prof Krogh in discussing the liability of whales to caisson disease[1] writes Supposing the whale to stay 5 minutes at 100 m the 1 000 litres of blood passing per minute would take up an extra amount of 100 litres and apparently calculates that diffusion would take place as readily at 100 m depth as at the surface of the sea I venture to think that he has overlooked an important consideration

Prof Krogh assumes and I think everyone who has considered the matter will agree with him that the air in the whale s lungs must stand at the same pressure as the water outside the thorax At 100 m the total pressure is about 11 atmospheres absolute so at that depth the whale s lung is compressed until an average alveolus has only one eleventh of the volum it had when the whale left the surface and began to dive This shrinking of the alveol must greatly decrease the surface available for diffusion and in addition the epithelium of the alveolus must become thicker still further hindering diffusion The effect of these changes is to obstruct the entrance of excess nitrogen into the blood when the whale is at a considerable depth and to favour its discharge when the animal is breathing at the surface

G C C Damant

---

[1] Nature 133 636 April 28 1934

THE point raised by Capt Damant is certainly important I have not found it possible to conjure up a mental picture of the whale s thorax and lungs compressed to one tenth or less and it becomes especially difficult when the air passages are taken into account since these must take up an increasing proportion of the total quantity of air available If the compression fails to interfere with the circulation I do not think that the diffusion of nitrogen or oxygen will be *very* seriously impaired M Krogh found that the diffusion in human lungs became independent of the volume when this was diminished below a certain point and explained this by the folding of the alveolar walls Such folding must take place to a very large extent in the lungs of the diving whale

The Giorgi System of Units

I REGRET to say my recent article on the Giorgi system[1] contained a mistake inexcusable I fear in the case of a pupil of Maxwell In the evaluation of K_0 I used electromagnetic instead of electrostatic units The value I gave needs dividing by v^2 the square of the velocity of wave propagation If we take 3×10^{10} cm per sec as the value of v then K_0 becomes

$$\frac{1}{4\pi}\,\frac{10^{11}}{9 \times 10^{20}} \text{ or } \frac{1}{36\pi}\,10^{-9}$$

and this is the value used by Prof Giorgi

I have to thank more than one correspondent for the correction

R T Glazebrook

Research Items

Ancestor Worship in Portuguese East Africa. An account of a village temple and ceremonial of WaBarwe ancestor worship by the Rev D Shropshire appeared in *Man* for May The temple was situated in a banana grove which was entered through a door way in a decorated bamboo screen It consisted of a small house, 7 ft by 5 ft , with a gabled thatched roof It was built of poles and reeds and had a small wicket gate of reeds Within the temple were two clay pots sunk in the ground A large banana leaf lay on the ground in front of them, and two small pieces of bamboo and a calabash hung from the roof An empty calabash upside down was inserted in the ground One of the pots was for offerings to the mothers of the forefathers of the head of the village, the other for the mother of his father In the ritual of worship the head of the village (or in this instance his deputy) swept the floor of the temple and its precincts He then placed a reed mat in front of the door of the temple and a new large clean banana leaf inside the temple in front of the two pots At a house in the village a procession was then formed which made its way to the temple, the wife of the representative of the village headman carrying mealie meal on a wooden plate On arriving at the temple all knelt and clapped hands ceremonially in greeting to the ancestors The deputy then entered the temple and sat on the ground After further clapping of hands he made offerings of the meal, with an invocation to each of the pots in turn The procession then returned to the house from which it started At the time of the great offering and worship of the ancestors at the sowing season, they offer beer, bananas and rice in addition to the mealie meal They do not pray to the Supreme Being except when out hunting, in prolonged drought or when the medicine man has failed to make a person well He is too far away, and on ordinary occasions they pray to the ancestors to intercede with him, instead of addressing him directly themselves

Tutelary Deities in Lower Bengal A village shrine sacred to two sister deities in a paddy field near Gangājaorā in the neighbourhood of Calcutta has recently been described by Dr Sunder Lal Hora (*J and Proc Asiat Soc Bengal*, N S 29, No 1) The two deities were installed in a small hut built on a low mud platform like a Mohammedan tomb They were represented by beautiful clay figures, dressed in fine and gorgeously coloured clothes The right arm of each was upraised in the attitude of benediction Nearby and on the platform were scattered earthen lamps and shells of coco nuts showing that some sort of *pūjā* had recently been performed there Inquiry elicited the information that the deities were worshipped on a day convenient to the whole village in the Hindu month of *Māgh* (January–February) They are known as *Olā*, *Jholā* and *Bŏn Bibi* *Olā* and *Jholā* are believed to be sisters, the former presiding over cholera, the latter over smallpox Their worship secures immunity for the village from these diseases *Bŏn Bibi* (lit the goddess of jungles) is worshipped to secure protection from jungle beasts The *pūjā* is a common affair for the whole village and the necessary articles are purchased from a common fund to which all contribute according to their means The principal item is the goat for sacrifice When it is beheaded, the head is taken as his fee by the blacksmith who performs the killing, while the remainder of the meat is distributed among the villagers The plot of land on which the *pūjā* is performed has been made over to the village in perpetuity by some rich villager The social status of the Pod caste, to which the villagers belong, is so low that high class Brahmans will not take food or water from the Brahmans who act as their priests An appended note by Dr S K. Chatterji adds that in Bengal, Hindu and Moslem frequently unite in worship of the cholera deity, when she is known as *Bŏn Bibi* as a concession to Moslem feeling

Parasitic Worms of Marine Fishes The attention of zoologists interested in the collection and determination of the parasitic worms of the marine fishes, and also of the marine birds and mammals, found in the British area, is directed to a recently issued section (Lief No 24, 1933) of Die Tierwelt der Nord und Ostsee" (Leipzig Akademische Verlagsgesellschaft m b H) which contains the parts of this work dealing with the Trematoda and the Acanthocephala The part on the Trematoda, by C Sprehn, includes useful tables for the discrimination of the 46 genera of Monogenea and of the 144 genera of Digenea which have been recorded from marine hosts taken in the area of the North Sea and the Baltic A total of 374 species is recorded and the host of each is stated The part on the Acanthocephala by D Wulker and J H Schuurmans Stekhoven, Jr , opens with an admirable summary, in about thirty pages, of the anatomy, life history and ecology of the group Lists follow of the invertebrate and vertebrate hosts of the worms, and keys are provided for aiding the determination of the orders families, genera and species The characters of the fourteen genera and 29 species recorded from the area are concisely stated. This part includes 54 illustrations , there are 20 in the part on the Trematoda

Hawaiian Cypræacea Dr F A Schilder in his paper Cypræacea from Hawaii" (*Bernice P Bishop Museum, Occasional Papers*, 10, No 3, 1933) investigates a large collection of 594 specimens and 19 species collected from Pearl and Hermes Reef, Laysan Island and French Frigates Shoal, Hawaii Most of them are well known shells but they are interesting as they show an extension in range of distribution, and the large number of individuals of many species makes possible the investigation of local variability by statistical methods The distribution of the Eratoidæ (Triviinæ) does not indicate any peculiarity With regard to the Cypræidæ, however, it is evident that the relatively large or callous species have been collected chiefly in French Frigates Shoal and in Laysan Island, whereas the smaller, less callous, or finely sculptured species occur chiefly in Pearl and Hermes Reef The difference, which is striking, indicates ecological differences in these islands. *Lyncina sulcidentata* seems to live equally well in both environments. There is no difference in the shells from Pearl and Hermes Reef All Eratoidæ are relatively small The Cypræidæ from Pearl and Hermes Reef are of medium size to small, or if larger they are always surpassed in size by those from French Frigates Shoal and from Laysan Island, where most species become large to gigantic

American Foraminifera Dr Thomas Wayland Vaughan completes the description of the species of the genus *Lepidocyclina* that have come into his hands during a number of years, thereby aiding in the solution of problems of geological correlation in the Mexican Gulf and Caribbean region in Studies of American Species of Foraminifera of the Genus *Lepidocyclina* ' (Smithsonian Miscellaneous Collections, 89 No 10 1933) The large and valuable material much of which was collected by the author himself from Mexico and Antigua helped by many others, and the collections from Cuba contain numerous species, and the account of them is practically complete These are from the Eocene, Oligocene and Antiguan formation *Lepidocyclina* is found to vary enormously and the difficulty of defining certain species is great The variations are of two kinds, first the difference due to alternation of microspheric and megalospheric generations, secondly the difference due to relative age Because of this large variation it is shown that many so called species are invalid This paper, which is a very valuable one, is illustrated by 32 photographic plates In the same periodical (Smithsonian Miscellaneous Collections, 89, No 11, 1933) Mr Donald Winchester Gravell describes some of the Tertiary larger Foraminifera of Venezuela

Evolutionary and Mutative Degeneration of Eyes in Gammarids Recently obtained results on the normal and mutant eyes of *Gammarus chevreuxi* (cf Wolsky and Huxley, *Proc Roy Soc London*, B, 114 , 1934 , see also NATURE, February 13 1932) make it possible to compare the mutative degeneration of eyes with the evolutionary process of eye degeneration in Gammarids This has been attempted by A Wolsky in a paper published in Hungarian (*Math Termt Ért Budapest*, 51 , 1934), which also gives a description of the loss of eyes in *Niphargus aggtelekiensis*, a recently discovered cave gammarid from the Aggtelek cave in northern Hungary The findings on this species confirm the general view held by various authors (Schneider, Vejdovsky, Strauss), that the evolutionary process of eye degeneration in Gammarids shows a centripetal tendency That is to say, the superficial elements of the eyes (crystalline cones) are affected first, and from these the degeneration proceeds towards deeper regions, finally affecting the optic nerve In *Niphargus aggtelekiensis* the eyes are entirely obliterated, but traces of the optic nerve are still present, although much reduced, and probably fused with elements of another nerve On the other hand, the eye reduction of *Gammarus chevreuxi* mutants (albino type) must be considered as centrifugal, because the elements affected most are the deeper ones (retinula, optic nerve and optic tract), whereas the crystalline cones, although highly degenerated are still present The embryological results confirm this, and indicate that in ontogeny degeneration starts at the junction between the base of the eye and the brain, and proceeds in both directions from this centre Thus the comparison does not support the view put forward by various authors (Banta, Nachtsheim), that blind cave species might have arisen from mutants with reduced eyes The mutations involved in evolutionary eye reduction must have been of other types than those which occur under laboratory conditions

Transmission of Streak Virus by a Leafhopper. At the East African Agricultural Research Station, Amani Dr H H Storey has shown that the leafhopper *Cicadulina mbila*, transmits the virus of streak disease from plant to plant of maize He has since found (*Proc Roy Soc* , B, 112, 46) that this vector capacity of the species is hereditary and that certain individuals do not possess it The hoppers when hatched are always non viruliferous and some of them are incapable of natural infection Pure lines of active and inactive insects were bred and crossed, the results of reciprocal crosses showing that the vector ability is inherited as a simple dominant sex linked Mendelian factor No difference could be found in the mouth parts of the two types In a further investigation (*Proc Roy Soc* , B, 113, 463) Dr Storey finds that after feeding on an infected plant the virus is present in the intestine but soon disappears from the rectal contents after they are voided In the 'active insect the virus can also be detected in the blood whereas in an 'inactive insect it is confined to the intestine The intestine wall of the latter therefore resists the passage of the virus but this may be overcome by puncturing the abdomen with a fine glass needle Some secondary mechanism must also be present since the frequency of success with this method is higher in active than in inactive insects An insect once infective remains so throughout its life In another species, *C zeæ* the inactive races were shown to be susceptible to inoculation by the same method

Fusarium Wilt of Asters A disease of China asters, which gives symptoms very similar to those of foot rot' or 'black leg , has been found in England by Messrs L Ogilvie and B O Mulligan (*Gardeners' Chronicle*, March 31, 1934 p 215) The causal fungus of foot rot was not present, and it was ultimately found that the asters were attacked by the fungus *Fusarium conglutinans* Two strains of the parasite were found—var *callistephi*, and var *majus* Symptoms are most conspicuous when the plants form their first flower buds Black areas extend from the base of the stem to the flower stalks, whilst the leaves turn yellow The plant ultimately wilts Trials with a large number of aster varieties have shown that English varieties are almost all susceptible, but an imposing list of American varieties which are resistant in Great Britain is given The disease appears to be the same as that known in the United States and in various European countries

Fungi Destroying Leather. The condition known to the leather trade as 'red heat' may cause loss to salted hides by producing thin spots of weak texture A study of the bacteria which cause this disease in Canada has been made by A G Lochhead (Bacterial Studies on the Red Discolouration of Salted Hides", *Canadian J Res* , 10, No 3, pp 275-286, March 1934) Two organisms were isolated—one was similar to *Serratia salinaria*, which causes reddening of cured codfish in eastern Canada, and the other was apparently a new species, named *S cutirubra* Both organisms can live on substrate containing relatively large quantities of salt, and are proteolytic They are considered to cause more damage than a species of red halophilic sarcinæ which was isolated from

Argentine hide. Non-chromogenic bacteria were also isolated from salted hide, but seem to be less injurious than those which produce the red colour.

Submarine Valleys. The submarine valleys of continental margins have generally been explained as having originated during a period of emergence and having retained their form for one reason or another during subsequent submergence. This origin, at least in relation to the submarine valleys of the coast of southern California, is questioned by the late Prof. W. M. Davis in the *Geographical Review* for April. Several of these valleys are continued to depths of 200–300 fathoms, which is considerably lower than Daly's estimate of the glacial lowering of sea level. Nor is there any evidence of upheaval or subsidence by that measure of height. Further, ordinary depositional processes which are building up the shallow sea floor ought to have obliterated at least the inner part of these valleys, but the reverse is true: some process is keeping these valleys open. Prof. Davis termed these valleys submarine mock valleys, since he does not believe they are due to subaerial erosion. He throws out the suggestion that the real explanation lies in a slow process of submarine erosion in rock disintegrated by a sea-floor current due to some peculiarity of coastal configuration and accelerated no doubt during stormy weather. This submarine erosion or marosion, as Prof. Davis termed it, might create a valley in the course of time and meanwhile of course no sedimentation would occur in it but only on either side. Monterey mock valley, seventy miles south of the Golden Gate, is cited as a typical example.

Architectural Acoustics. The issue of the *Journal of the Franklin Institute* for April contains the address delivered before the Institute in December by Dr. Paul E. Sabine on recent developments in architectural acoustics. Since Prof. Wallace Sabine of Harvard, the founder of the subject, gave an address on it nineteen years ago, great improvements have taken place in both the production and the measurement of the intensity of sounds of all audible frequencies, mainly due to the vacuum tube and amplifier, and we now know that the response of the ear to a sound is proportional to the logarithm of the intensity of the sound. So far as sound insulation is concerned, it is now established that materials like felt reduce the sound transmitted through them to a much smaller extent than solid walls, 4 in. of felt giving less reduction than one inch of solid plaster. The transmission through walls and partitions depends on their forced vibrations, and the sound reduction produced by them is very nearly proportional to the cube of the weight per square foot of wall. In the case of double walls or partitions, structural connexion between the two should be avoided and one of them should be of the heavy and the other of the light type.

Isotopic Separation by Electrolysis of Water. It is known that the lighter hydrogen isotope is evolved preferentially when an alkaline solution is electrolysed, and Polanyi has concluded that this is due to a difference of overpotential for the deposition of H^1 and H^2 on the cathode. R. H. Fowler (*Proc. Roy. Soc.*, A, April) has examined alternative mechanisms for the preferential evolution. He writes equations for the concentration of hydrogen ions in different parts of the cell in steady electrolysis. The self-diffusion of the water is apparently sufficient to keep the ratio of heavy to light hydrogen normal near the cathode in spite of the different mobilities of the ions. In addition to the mechanism proposed by Polanyi, however, there may be differential rates of molecule formation by combination of atoms at the cathode surface. It may be noted that Polanyi's mechanism is not consonant with Gurney's theory of electrolysis, while the theory is not inconsistent with the alternative explanation.

Crystal Structure of the Heusler Alloys. The Heusler alloys are remarkable in that they become ferromagnetic after suitable heat treatment, although they contain only non-ferromagnetic elements (copper, manganese and aluminium). A. J. Bradley and J. W. Rodgers (*Proc. Roy. Soc.*, A, April) have investigated the alloys by X-ray crystallography in order to find if the ferromagnetic behaviour is correlated with a particular crystal structure. The annealed alloys (non-magnetic) mainly show a structure like that of a γ-brass, but the quenched specimens (magnetic) show a body-centred cubic structure with a face-centred cubic superlattice. The further investigation of this structure was carried out by careful intensity measurements on powder photographs. It was found possible to distinguish the positions of the copper and manganese atoms by observing the powder patterns with iron, copper and zinc *K* radiation, since the scattering power of an atom for X-rays varies rather rapidly in the neighbourhood of an absorption edge. This is a new method which may have important applications. The magnetic alloys have a structure in which copper, manganese and aluminium atoms occupy quite definite positions in the lattice, but when the composition of the alloy differs from Cu_2MnAl the positions normally occupied by atoms of one element may be replaced according to definite rules by those of another, the structure remaining homogeneous.

Lubricating Grease. Choice between grease and oil is a vital problem in industrial plant lubrication to-day and cannot be made without a comprehensive knowledge of physical characteristics and behaviour of the lubricants in question, as well as an understanding of prevailing operating conditions. Much work already done on lubricating oils has led to their several varieties being classified and their characteristics standardised. With greases, however, this is not the case, since until recently they were regarded merely as an outlet for by-products of the petroleum industry and not assessed on their true value as lubricants. H. S. Garlick, in a paper read on May 8 before a meeting of the Institution of Petroleum Technologists, stated that the most convenient method of classification of greases is according to the soap used in their manufacture; thus, the main types are lime, soda, lead and aluminium base greases, with a fifth class of miscellaneous types and special products. In all cases consistency, melting point (flow point), stability both in storage and in use, colour, odour and load-carrying capacity of greases should be determined under known conditions and by accepted methods before application and, in circumstances where the manufacturer or user may require fuller information, exhaustive physical and chemical analyses should be carried out. Unfortunately, research on lubricating greases has not yet reached a point where standard methods of testing can be fixed.

The Royal Observatory, Greenwich

Annual Visitation

THE annual meeting of the Board of Visitors of the Royal Observatory, Greenwich, was held on June 2 The outstanding feature of the report, presented by the Astronomer Royal, Dr H Spencer Jones, is the announcement of the completion and erection of the new 36 in reflector the gift of Mr W Johnston Yapp The new telescope was formally opened by the First Lord of the Admiralty on the afternoon following the Board meeting

On the occasion of the formal opening, Dr Spencer Jones referred to the generosity of the donor, and to the fact of the gift having been made in recognition of the work of his predecessor Sir Frank Dyson The telescope is not, of course, nearly so large as the giant reflectors in use in the United States, but it is as large as might profitably be installed at Greenwich, on the fringe of the great smoke cloud of London As an instance of Dyson's eagerness in following up new avenues of astronomical work, Dr Spencer Jones reminded his hearers that during the darkest hours of the War Sir Frank organised an eclipse expedition in order to make use of the favourable eclipse of 1919 at which the general relativity theory might be tested Despite the short interval which elapsed between the end of the War and the eclipse and despite the great difficulties of the times, an expedition was successfully organised parties being sent from Greenwich and from Cambridge The success of these expeditions in establishing the observational evidence for the general relativity is well known

Sir Frank Dyson who spoke next, paid a tribute to the keenness and enthusiasm of his staff, which he said, had contributed very materially to the progress of the Observatory under his direction The First Lord then formally accepted the gift on behalf of the Admiralty which, he said, is very proud of its connexion with Greenwich

The new telescope is fully described in the May issue of the *Observatory*, and also in the *Engineer* of May 18 and 25 by courtesy of which we are reproducing a general view of the instrument (Fig 1) It may be said here that the great mirror, which was cast by the Parsons Optical Glass Co Derby, is of 36 in aperture and has a focal length of 15 ft The instrument is intended primarily for use in the Cassegrain form and there is a hole 7 in in diameter, in the great mirror The secondary mirrors, of which there are two are made of fused quartz The secondary mirror which is in use at present is convex and has an aperture of 7 in and a focal length of 30 in Set 30 in inside the principal focus of the great mirror it sends a parallel beam on to a slitless spectrograph The alternative secondary mirror is also convex but has a diameter of 11 in and a focus of 75 75 in It will be set 50 in inside the principal focus and will be used to project a real image of a star on to the slit of a slit spectrograph The equivalent focal length of this arrangement is 45 ft

The slitless spectrograph is actually in use It was constructed by Messrs Hilger, Ltd It takes a 6 in parallel beam through a single 45° prism The refracted beam is focused by a 9 in concave mirror of 36 in focus placed about 36 in behind the prism The returning rays are deflected by a flat to a camera at the side of the spectrograph The use of a mirror instead of a lens is designed to give perfect focus over a large range of wave lengths, as the instrument will be used to continue the Greenwich work on colour temperatures of stars The light grasp of the combination of telescope and spectrograph is such that a well exposed spectrogram of a star of magnitude 3 0 is obtained in three minutes The instrument was brought into use on April 20, and the report of the Astronomer Royal mentions that 19 comparisons of 12 stars with standard stars (for colour temperature) have been secured on four nights Attention will be concentrated on stars from types *O* to *A*0 down to the fifth magnitude

The mounting of the telescope is the modified English form A long polar axis is supported by piers resting on very solid concrete foundations at the north and south ends and carries a crosshead to which the telescope is attached The general arrangement resembles the mounting of the 72 in reflector at Victoria B C, but the Greenwich polar axis is so long—21 ft—that the whole telescope can pass under it if desired All the bearings are in ball races and the telescope moves with great ease It can be turned in Right Ascension and Declination by electric motors both quick and slow motions being provided in each co ordinate The telescope proper consists of a heavy casting to which is attached the mirror cell and an open work tube which supports the secondary convex mirror The dome is 24 ft. in diameter and provides ample room in which to work the telescope It is built of a steel frame covered with papier mâché and sheathed with copper The dome is rotated by a continuous cable operated by an electric motor There is a silvering room for the great mirror, which will be carried there on a special trolley

The instrument is by Messrs Grubb, Parsons and Co and the building was erected by the Civil Engineer's Department of the Admiralty A slit spectrograph has been designed for use with the instrument This will have three prisms made of a glass transparent in the ultra violet, but an alternative camera for use with one prism alone will be provided

Turning to other features in the Astronomer Royal's report it is noted that progress has been made with the new transit circle, which is being constructed by Messrs Cooke, Troughton and Simms Ltd The house for this instrument has already been erected This is semi cylindrical in shape, the axis of the cylinder coinciding with that of the transit circle and the interior diameter being 30 ft Two shutters, which are opened by electric motors, give an aperture of 8 ft in the meridian The housing is covered with copper sheeting over a layer of compressed cork slabs, three inches thick, to give thermal insulation

During the past year, meridian observations of the sun were secured on 148 days and of the moon on 100 days The mean correction to the moon's longitude from Brown's tables has decreased still further It is now +4 2″ Two hundred and eighteen plates for latitude variation were taken with the Cookson floating telescope, and 358 observations of 227 double stars were secured with the 28 in equatorial The parallaxes of 32 stars were determined

The work with the 30 in reflector on the colour temperatures of the stars was continued until the Yapp reflector was ready to supersede the older instrument Attention has been concentrated on re determining the zero point of the Greenwich colour temperature system The acetylene burner formerly employed has been replaced by an Osram unifilar tungsten filament vacuum lamp, which was calibrated at the National Physical Laboratory at the beginning and at the end of the programme The combined results of the old and new determinations of colour temperature of standard stars, which agree very well with one another, give a temperature of 18000° K for *A*0 stars

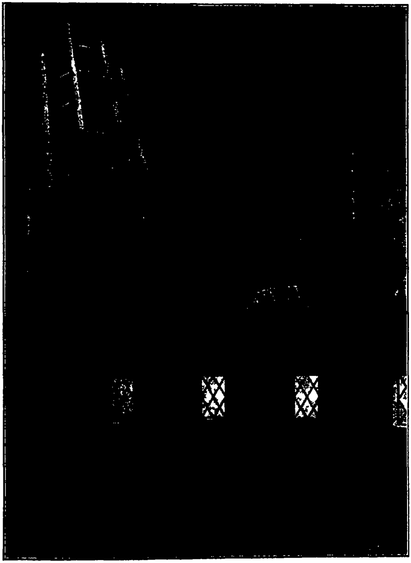

FIG 1 The Yapp 36-in reflector at the Royal Observatory Greenwich

The measurement of plates taken at the 1930–31 opposition of Eros is proceeding Photo heliographs of the sun have been obtained on 271 days, and observations with the spectrohelioscope on 190 days The frequency curves of the Greenwich observations of radial velocities of dark flocculi associated with sunspots have been plotted and are found to be in agreement with the predictions of Chandrasekhar's recent theory of the chromosphere Sunspot activity has been slight The new sunspot cycle however, appears definitely to have commenced Magnetic and meteorological records have been kept, as usual, by the Observatory the former having been secured at the magnetic station at Abinger The mean magnetic elements for 1933 at Abinger were Declination, 11° 51 7 W , Horizontal Force 0 18532, Vertical Force 0 42942 Dip 66° 39 4

As is well known, last year was marked in Great Britain by a great scarcity of rainfall The total rainfall at Greenwich for twelve months ending 1934, April 30, was 16 96 in , which is 7 28 in less than the average for the years 1841–1915 In view of special interest attached to observing conditions in England apropos the advisability or otherwise of erecting large telescopes in Great Britain rather than in South Africa it may be noted that the sky was completely unclouded on 41 nights only in the entire year

Special interest is attached to the time determinations at Greenwich during the past year as an international longitude programme was organised in October November 1933 in which Greenwich took an active part A new type of chronograph with a very light syphon pen and a tape running at 2 5 cm per sec instead of the old fashioned barrel has been installed It is now estimated that the probable error to be attached to each determination of time is 0 010^s but that there are still personal equations to be attached to individual observers in spite of the use of the moving wire micrometer Two of the routine observers differ from one another by 0 04^s At present the mean of three regular observers is taken as standard for Greenwich Mean Time It is hoped to construct a personal equation machine in the future Meanwhile a cathode ray oscillograph has been purchased with which it is intended to investigate time lags in the reception of wireless time signals

Spectroscopically Pure Substances

About ten years ago Messrs Adam Hilger Ltd, the well known firm of optical instrument makers first undertook to place on the market substances of a high degree of purity such as could be relied upon for the exacting requirements of spectroscopic work It was intended that such supplies should not only be the purest obtainable by modern technique but should also be accompanied by a detailed report of the exact amounts of residual impurities as measured by both chemical and spectroscopic methods In some cases indeed so pure have been the products obtained that only quantitative spectroscopic analysis has been available Messrs Hilger have obtained their supplies from specialists in all parts of Europe and the United States and they have been produced in the laboratories of universities technical institutes industrial works and of private individuals as well as from the National Physical Laboratory

Up to 1932 metals alone had been produced but recently oxides and salts have been added to the list Of these highly purified materials some twenty two are metals eleven are rare earths and the remainder are largely commoner salts and oxides The magnitude of this achievement and the considerable advance in the technique of both preparation and analysis made in recent years may perhaps best be judged from the facts relating to a few typical substances

Manganese This metal has been prepared in the National Physical Laboratory according to the formula of Dr M V Gayler A high frequency induction furnace is used to distil the metal at a temperature just above its melting point (1244° ± 3° C) at a pressure of one or two mm Brittle silver grey nuggets obtained in this way were found to have a purity of 99 99 per cent The principle impurities were aluminium (0 0003 per cent) iron (0 0024 per cent) nitrogen (0 0027 per cent) and phosphorus (0 0007 per cent)

Germanium has been prepared in the laboratories of the Sir John Cass Technical Institute of at least 99 98 per cent purity The impurities found were iron (less than 0 001 per cent) and sulphur (0 002 per cent)

Cadmium and Zinc Both of these are of exceptional purity, namely, of more than 99 999 per cent The zinc contains copper (less than 0 0001 per cent) lead (about 0 0002 per cent), and slight traces of calcium and iron The cadmium contains traces of bismuth, lead and copper in each case to an extent of less than one part in a million

Columbium of 99 8 per cent purity has been prepared According to Dr W F Meggers the metal is free from the frequently associated elements vanadium tantalum zirconium and molybdenum and contains as impurity chiefly tin—which is not of great inconvenience from a spectroscopic point of view

Iron rods obtained electrolytically with a purity of 99 96 per cent are available These contain 0 02 per cent of non metals (of no spectroscopic interest) silicon (0 01 per cent) and 0 01 per cent of various metals of which full details are supplied

Silver with a purity of 99 999 per cent is probably one of the purest substances produced It has been freed entirely from copper and contains as residual impurity chiefly calcium

Gallium with a purity of 99 938 per cent which contains only 0 05 per cent of zinc is probably the purest specimen of this element so far produced

Copper rods of 99 964 per cent purity have been obtained Of the impurities oxygen accounts for 0 03 per cent and the remainder is constituted of various metals in very small amounts. Very recently Messrs Hilger have obtained supplies of copper of which the impurities are only about one twentieth those quoted above

We turn now to a few chemical compounds which are made available under the trade name of Specpure substances

Beryllium Oxide and Chloride of 99 99 per cent purity contain only iron (0 005 per cent) with a trace of sodium and a minute trace of magnesium These compounds have been hitherto very rare in a highly purified form

Calcium Chloride is notable for its high general purity of 99 993 per cent and especially for its complete freedom from strontium The latter achievement must be rare if not unique since Hönigschmid's recent atomic weight determination was made on material not quite free from strontium

Similarly chlorides of strontium aluminium and cobalt and also powdered silica all of 99 99 per cent purity can be supplied Lead nitrate with a purity of 99 999 per cent and containing only traces of bismuth copper and antimony is also noteworthy

These illustrations will suffice to show the excellence and range of the materials now available A new standard of purity has been introduced on an extensive scale, and Messrs Adam Hilger deserve the congratulations and thanks of physicists and chemists alike for their enterprise and its well merited success

Heavy Hydrogen

THE April issue of the *Journal of the American Chemical Society* contains some communications on the subject of heavy hydrogen and heavy water (names used by the authors) H S Taylor and Selwood announce an error in the calibration of apparatus which makes the viscosity previously reported erroneous, the correct value is 12 6 milli poises at 20° The ratio of specific gravities of heavy and light waters at 25° is 1 1079 whilst Lewis and Luten give 1 1056 Pure D_2O apparently readily takes up moisture from the atmosphere The ratio D_2O/H_2O in natural water is about 1 in 5000–6000 in agreement with the mass spectrograph results of Bleakney and Gould

Dole reports that the water formed by the combustion of kerosene benzene and honey was 7 8 and 4 parts per million respectively heavier than ordinary water whilst Washburn and Smith had found that water from the combined hydrogen of a willow tree was 5 to 6 parts per million heavier G N Lewis and Hanson show that the vapour pressures of mixtures of H^1_1 and H^2_1 approximate closely to Raoult s law and the temperature at which freezing begins also proved to be nearly linear with the mole fraction While the solid phase is richer in H^2_1 than the liquid the difference is not great say 0 55 mole fraction for the solid when that of the liquid is 0 50

The same investigators also report measurements of the vapour pressures of pure H^2_1 and mixtures of H^2_1 and H^1_1 in a separate communication The triple point of H^2_1 is 45 40 cm and 18 66° *K* An equation of state for H^2_1 is to be published later When H^2_2O is treated with sodium a considerable amount of H^1_1 is present which came from the sodium Lewis and Schutz have measured the vapour pressures of liquid and solid H^2CN those of liquid H^2CN differ very little from those of H^1CN The freezing point of H^1CN is 259°*K* and of H^2CN 261°*K*

The same experimenters find that the ionisation constant of deutacetic acid in heavy water is less than one third as great as that for ordinary acetic acid in common water which indicates that $(H^2)^+$ is much more firmly held by a pair of electrons of another atom than is a proton

University and Educational Intelligence

CAMBRIDGE —Mr A J Berry of Downing College has been appointed University lecturer in chemistry and Dr C P Snow of Christ s College University demonstrator in chemistry Mr J A Ramsay of Gonville and Caius College has been appointed University demonstrator in experimental zoology J H Halliday of Downing College and J F Everett of St John s College have been nominated to use the University s table at the Zoological Station at Naples

Applications for the E G Fearnsides scholarship for clinical research on the organic diseases of the nervous system must be sent to the Registrary before June 27

The Master and fellows of Pembroke College announce that the Stokes studentship, of the annual value of £400–450, will shortly become vacant Candidates should send their applications to the Master before June 23 They must have shown capacity for research in mathematical or experimental physics or in subjects cognate thereto such as physical chemistry or the study of physical laws in relation to living matter

OXFORD —In presenting Dr Edwin Powell Hubble of the Mount Wilson Observatory for the honorary degree of D Sc on May 29 the Public Orator Mr C Bailey recalled the fact that Dr Hubble is a former Rhodes scholar at Oxford Referring to the great telescope at Mount Wilson as a structure worthy of giants he directed attention to Dr Hubble s researches on remote nebulæ and made especial mention of his conclusions as to the speed with which they are retiring from our view The Vice Chancellor addressed Dr Hubble as illustrious among the illustrious masters of astronomy and as a revealer by his penetrating sagacity of the secrets of the universe

Mr Battiscombe Gunn curator of the Egyptian Section of the University Museum Philadelphia has been appointed professor of egyptology in the University to hold office from October 1

THE Science Scholarships Committee of the Royal Commission for the Exhibition of 1851 have made the following appointments to senior studentships for 1934 —On the recommendation of the University of Cambridge Mr C H Waddington for research in biology and Dr C B O Mohr for research in physics On the recommendation of the Imperial College of Science London Dr J D Solomon for research in geology On the recommendation of the University of Oxford Mr S G Hooker for research in applied mathematics On the recommendation of the University of Aberdeen Dr D J Bell for research in physiology

UNIVERSITY COLLEGE London continues to attract students from all parts of the world in increasing numbers Its recently issued annual report shows that of 3 121 students enrolled in 1932–33 56 per cent were from homes within 30 miles of the College 24 per cent from elsewhere in the British Isles 9 per cent from the rest of the Empire and 11 per cent from the rest of the world India Ceylon and Burma contributed 169 (including 57 post graduate and research students) China and Japan 24 Palestine 16 four other Asiatic countries 23 Germany 55 (including 12 vacation course students) Scandinavian countries 30 Holland and Belgium 25 Switzerland 23 France 20 Italy 15 thirteen other European countries 60 the United States 45 Canada 15 West Indies 12 Australia and New Zealand 41 (33 postgraduate) South Africa 20 Egypt 19 seven other African countries 16 The total number of postgraduate and research students was 496 being 31 more than in the preceding year The medical student enrolment also showed a notable increase from 200 to 230 The most conspicuous decrease was in the department of fine arts from 299 to 253 chiefly women The enrolment of students for the current session up to January 31 was 3 000 as compared with 2 862 at the corresponding date of 1933 The report refers to the completion of the new accommodation for the reorganised Department of Zoology and Comparative Anatomy which it is claimed is alike in planning and equipment second to none in Great Britain

Science News a Century Ago

H.M.S. *Beagle* enters the Pacific

For about two and a half years, H.M.S. *Beagle* under Capt. FitzRoy had been engaged on the exploration of the eastern shores of South America including Patagonia, the Falkland Islands and Tierra del Fuego, but in June 1834 the ship passed from the Atlantic to the Pacific and started on that part of her voyage which was to carry her to Tahiti, New Zealand, Australia and home by the Cape of Good Hope. Weighing anchor on June 8, the vessel left Port Famine and proceeded down the Magdalen Channel, "that gloomy passage which", says Darwin, "I have before alluded to, as appearing to lead to another and worse world". On the evening of that day the ship anchored at Cape Turn close to Mount Sarmiento the highest peak in Tierra del Fuego and the passage was resumed next day in good weather. By night, however, the western part of the channel had been reached, "but the water was so deep that no anchorage could be found. We were in consequence obliged to stand off and on in this narrow arm of the sea, during a pitch dark night of fourteen hours long". On June 10 Darwin says, "In the morning we made the last of our way into the open Pacific. The western coast generally consists of low, rounded barren hills of granite and greenstone. Sir J. Narborough called one part South Desolation because it is 'so desolate a land to behold', and well indeed might he say so. One sight of such a coast is enough to make a landsman dream for a week about shipwrecks, peril and death, and with this sight we bade farewell for ever to Tierra del Fuego."

Sir James South's Telescope

In his autobiography, Airy records that on June 14, 1834, "I went to London, I believe for the purpose of trying the mounting of South's telescope as it had been strengthened by Mr. Simms by Sheepshanks's suggestions. I was subsequently in correspondence with Sheepshanks on the subject of Arbitration on South's Telescope, and my giving evidence on it. On July 29th, as I was shortly going away, I wrote him a Report on the Telescope to be used in case of my absence. The award, which was given in December, was entirely in favour of Simms." South, who was born in 1785 and died in 1867, was a London surgeon who through his friendship with Joseph Huddart (1741–1816) became an amateur astronomer. His first observatory was in Southwark and his second, built in 1826, on Campden Hill, Kensington, where he had a "princely collection of instruments such as have never yet fallen to the lot of a private individual". His work gained for him the Copley Medal in 1826 and the presidency of the Royal Astronomical Society in 1829. About this time he purchased a 12 in. object glass made by Cauchoix from glass supplied by Guinand, and employed Edward Troughton (1753–1835), then in partnership with William Simms (1793–1860), to construct an equatorial telescope for it. The mounting unfortunately did not prove successful, and after an attempt at arbitration the matter went into the courts and led to "the most remarkable astronomical trial which ever took place in England". South, who was of a very litigious nature, was so embittered by losing the case that he broke up the instrument, placarded the walls of his observatory with an extraordinary bill and sold the debris by auction. Fortunately the object glass was not destroyed. In 1862, South presented it to Trinity College, Dublin, and it was afterwards used by Brünnow and Ball at the Dunsink Observatory.

Thilorier's Experiments on Carbonic Acid

Faraday succeeded in 1823 in liquefying carbonic acid, and in 1834 Thilorier obtained it in the solid form of 'snow'. Thilorier, the details of whose life do not appear to be known, contributed several papers to the Paris Academy of Sciences, one of which was read on June 16, 1834. In a report of this paper the *Athenæum* said: "M. Thilorier presented for inspection a machine for obtaining chemically, and in a short time, a quart of carbonic acid; the memoir presented a variety of experiments upon this almost intangible liquid, since it can only be procured in vessels hermetically sealed. M. Thilorier announces that in gases the pressures at different degrees of temperature do not correspond with the densities, as is generally believed. Liquid carbonic acid, he says, is of all bodies, that which dilates and contracts itself the most under the influence of atmospheric variations in temperature. Its enormous power of dilation points it out as a new principle of movement far more powerful than any hitherto applied. It is also the liquid that produces the greatest depression of temperature. Directing a jet of it on the ball of a thermometer of spirits of wine, it reduced it to 75° below zero, the greatest depression hitherto observed being 68°. M. Thilorier intends to apply this liquid to an air gun."

Societies and Academies

London

Royal Society, May 31. A. F. W. Hughes: Development of blood vessels in the head of the chick. The development of both arteries and veins in the head of the chick from the stage of two days of incubation to that of hatching is described, thus continuing the previous account of Sabin, whose methods have been employed in the present study. The simultaneous study of both arteries and veins has thrown light on the well known fact that one type of vessel tends to accompany the other in adult anatomy. Frequently a nerve also enters into this relationship. Such a complex has been found, in the head of the chick, to develop from a capillary plexus developed along the course of a nerve, out of which both an arterial and a venous channel differentiate. There is evidence that in other vertebrates, and in other regions of the body, similar developmental processes take place. Questions of vascular homology, and current theories on the developmental mechanics of the circulatory system are discussed in the light of the facts which this study discloses. The suitability of the embryonic vascular system as an object of experimental embryological study is stressed. A. Farkas, L. Farkas and J. Yudkin: Decomposition of sodium formate by bacterium coli in the presence of heavy water. The isotopic composition of the hydrogen evolved from mixtures of heavy and ordinary waters with sodium formate by the action of this organism has been analysed. Its composition is defined by the equilibrium $H_2O + HD \rightleftharpoons HOD + H_2$. Since the gas liberated is in equilibrium as defined by the equation

$H_2 + D_2 \rightleftharpoons 2HD$, the generally accepted mode of decomposition of sodium formate by the hydrogen lyase must be wrong and either atoms or radicals must be involved Palladium black behaves in a similar manner The importance of this equilibrium in the preferential liberation of light hydrogen in electrolytic and chemical reactions is emphasised

Population Problems

THAT population size and composition exert a profound influence on many of the social political and economic problems which beset a nation and that it will be possible to make a fairly accurate forecast of changes in these qualities at different times in the near future though well established is not generally understood Hence addresses such as the recent Huxley Memorial Lecture on the Restrictive Law of Population by Prof Johan Hjort* and publications such as the newly issued broadsheet of P E P on Future British Population † are to be welcomed and commended to the notice of all those who for this reason or that must now in 1934 take account of the warrantable view that in 1976 the population of Great Britain will be less than perhaps far less than 33 million and that in it the children will be outnumbered by the old The voice that then will make itself heard will be that of secure senescence and largely female at that In 1901 there were 12 million children in Great Britain in 1951 there may be just over 6½ million the present number of women of sixty five years of age and over will be doubled during the next fifty years and will increase by 50 per cent within the next seventeen

Times have changed and changed considerably since the publication of the Essay on Population There is no longer any danger of the means of subsistence becoming disproportionate to the number of human individuals dependent on them for thanks to developments in the methods of food production the relation of man to the resources of his environment has been completely reversed We can produce food of the highest quality in quantity far in excess of the needs of the sum total of human individuals at present living on the earth we can force temperature humidity and light into harmony with our various requirements Thanks to chemistry we are becoming more and more freed from our dependence upon animals and plants for commodities that are essential to our well being and furthermore through developments in reproductive physiology we are now able deliberately to control the reproductive rate of a human society

Thus it is that the Malthusian threat of over population has lost much of its force in fact in most European countries, and in the United States of America, already in its place there is an increasing fear that the peoples are failing to maintain themselves numerically In Great Britain the population is already ceasing to increase, and if no further change in the fertility and mortality rates occurs it can be assumed that a stable age composition in the population will ultimately be reached, and that thereafter the population in each subsequent generation will become progressively perhaps even alarmingly, diminished Indeed it may dwindle away in spite of all improvements in personal and public hygiene which tend to reduce mortality All the evidence that is available shows that such speculations as these are entirely warrantable

---

* The Restrictive Law of Population By Prof Johan Hjort (Imperial College of Science and Technology Huxley Memorial Lecture, 1934) Pp 46 (London Macmillan and Co Ltd 1934) 1s net

† Future British Population Planning No 27 May 22 1934 (P E P 16 Queen Anne's Gate London S W 1)

It becomes a matter of supreme importance, therefore to those who wish to see the continuance of ourselves as a people, to inquire into the causes of the numerical decline of a population It is necessary to ask and to answer such a simple question as why it is that people have children at all The child, which seems to be regarded as a welcome reinforcement by those who speak in the name of the State, as often as not is looked upon by the parent as an inconvenient burden It seems to be commonly suggested that man and especially the female of the species, exhibits a definite biological urge toward reproduction This may be, but the view has no experimental foundation, and its investigation is complicated by the fact that, in our society at least, the mother enjoys certain economic and social advantages Of all the factors which are recognised as affecting the reproductive rate of a people, it is generally agreed that the one which is mainly responsible for the dwindling of a population is the progressive fall in the average number of children born to each married woman, and it would seem to be established that a people of which the average woman has less than one female offspring is doomed to extinction

It must remain an unanswered question for the moment as to whether or not it matters very much to the world as a whole and to its further evolution that a particular people, through progressively falling fertility, should disappear All that we can do is to search for information into the causes that operate in the production of a dwindling population in order to obtain a knowledge of the factors involved, so that this may be made available for incorporation into any programme relating to population size which may be formulated in the future Manifestly, the problem stated in its simplest terms is that of removing such obstacles to parentage as exist in a particular society

A great many facts relating to the growth of human populations are already in our possession but concerning their explanation there is still much disagreement We know that, in general the reproductive rate in an industrialised community is lower than that in an agricultural that a preponderance of Catholics in a community is commonly associated with a high fertility that the reproductive rates of people living under different social conditions and belonging to different occupational classes differ more or less widely one from the other But to find a satisfying explanation for these facts is not simple If Roman Catholics are remarkable for their high fertility the Jews, who have a sex ethic that is comparable show a low reproductive rate The differential fertility of the different social classes and of the rural community as compared with the urban may be nothing more than evidence that differences in the social environment can yield differences in the expression of certain biological variables

It has not yet been shown that removal of inequalities in the environment would not produce equality in respect of reproductive rate Indeed there are reasons for holding the view that the differential fertility of the social classes is tending to disappear It has been too easily assumed perhaps, that a widespread use of contraceptives is in itself a sufficient explanation of a falling birth rate It is difficult to accept this statement in view of the fact that legalised abortion and active birth control propaganda in the U S S R do not seem to affect the growth of a people eager and able to expand

One thing is certainly true, and that is that a population can only maintain itself if every woman in it bears on the average three children This of course means that whilst many will bear none, others must bear four and five, and the problem facing those who wish to see our population maintain its present level is that of obtaining in the population a sufficient number of more-than three-children families

It may be assumed that in Great Britain, as in other countries, a low fertility is the result of urbanisation In the social structure, with its tradition which appeals to the incentive of private profit, and in which there are great inequalities in respect of wealth, with an improvement in the standard of living of the people, there have come into being many and varied distractions which can be regarded as alternatives to parenthood The political emancipation of women and their desire for economic liberty have resulted in competition between women and men in businesses and professions, and motherhood no longer offers a satisfactory career to great numbers of women The standards of feminine beauty require habits and physical attributes which cannot easily be harmonised with the realities of child bearing and undoubtedly one of the most important factors which tend to cause family limitation has been the conferring of an economic advantage upon persons who exhibit a low reproductive rate There are in Great Britain hundreds of young married couples who are determined not to have children, at least yet awhile for the simple reason that conditions of life being as they are they much prefer to have other things

The economic barriers to fertility can be overcome by such measures as family endowment, which removes the economic inequality between those who have many children and those who have none, by ruralisation, by giving leave on full pay to women in confinement but when these things have been done there still will remain the underlying psychological causes of self imposed sterility In days gone by when distractions were fewer, when children were an asset, when the man with a quiver full was most highly respected, when opportunity was plentiful, there being no reason to doubt that the child would enjoy the same opportunities as did his parents, it mattered not that sexual activity was so commonly followed by reproduction But in these days, it is becoming increasingly common for parentage to cease to be a casual affair and to be a matter of deliberate choice In the future there will be no such thing as an unwanted child The problem, in its ultimate analysis, therefore comes to be that of cultivating the wish to have children, and of creating a type of society in which the child shall have a definite function

If the population of Great Britain dwindles, it will not be because our descendants will be less fecund than were our ancestors, but because they will choose, or will be forced, for economic or other reasons, to limit the number of children entering into an unsatisfactory environment When the world is fit for children to live in, they will be born, whilst things are as they are, it is perfectly reasonable to limit their numbers

Experiment and Theory

Molecular Hydrogen and its Spectrum By Prof Owen Willans Richardson (Yale University Mrs Hepsa Ely Silliman Memorial Lectures) Pp xiv+343 (New Haven, Conn Yale University Press, London Oxford University Press, 1934) 13*s* 6*d* net

ANYONE seriously engaged in the pursuit of scientific knowledge and with a mentality broader than that of the self sufficient 'research worker, will at one time or another have been confronted with the question as to the importance of his own investigations Aside from the viewpoint *sub specie aeternitatis*, from which the playing of the child in the sand and the discovery of the laws of the physical world appear equally important —or unimportant if one prefers—this question will by everyone be admitted to be entirely justified An answer may perhaps be given in somewhat the following way the more radical the change in our theoretical notions which an experiment necessitates, the more important the experiment, the larger the group of hitherto unexplained facts to which a theory opens an interpretation, the more important the theory In these times, when new scientific views penetrate quickly, the frequency with which a scientific publication is quoted by investigators (other than its author) may serve as a quantitative measure of this importance

Looking at the modern scientific output, one must confess that a good deal of experimental work done to day is bound to fall into oblivion rather quickly But while this work still represents a certain amount of conscientious labour and there is, as with a defaulted bond issue, always still a chance that it may become of value there is no such excuse for the airy castles of speculation of those who forget that the mathematics of the theoretical physicist is a necessary evil and that an accumulation of equations without a physical idea, related in a recognisable way to the empirical reality, does not deserve to be called a theory

Prof Richardson is one of the enviable persons who have been able to combine experimental research with theoretical investigation, and through this fortunate circumstance to advance physical science in very diverse directions The present book, devoted exclusively to the hydrogen molecule and its spectrum, and to a large extent a summary of his own work, illustrates clearly the interaction between experiment and theory Here is a mass of experimental facts, a spectrum of so involved an aspect that for a long time it was neither classified as a line spectrum nor as a band spectrum, but put into a category all by itself under the name of many lined spectrum Only on the basis of the firm belief that the interpretation of the evidence from so simple an atomic system as H_2 must in the end appear simple itself could give the courage to tackle the analysis of the spectrum in question This conviction has been fully rewarded, and indeed, the complete understanding of the structure of this simplest of molecules thus obtained has been material in the elucidation of a number of other problems that had long been puzzling to the physicist

In the earlier chapters of the book the reader is made acquainted with the various quantum numbers and symmetry properties that serve to classify the stationary states of a diatomic molecule Then the selection and intensity rules are discussed, which determine so markedly the character of a band spectrum Regarding the application of the theory to the experimental facts as carried out principally by Richardson and his pupils, by Dieke and by Weizel, it should be stressed that we owe to Prof Richardson the clear recognition of the two non intercombining term systems of H_2 as singlet and triplet-systems as well as a trustworthy spectroscopic determination of the dissociation energy of the H_2 molecule in its ground state, a quantity of great interest both to the physicist and to the chemist, the value of which had been oscillating for a number of years between rather wide limits Also the term system of H_2, besides that of He_2, furnishes an interesting illustration of the phenomenon of *L* uncoupling

The determination of the electronic levels of H_2 was of great importance in connexion with the theory of chemical binding which Heitler and London originally developed for this molecule, and led Hund to a complete level diagram connecting the atomic and molecular states of hydrogen The analysis of the H_2 spectrum was also essential in the discussion of the intensity alternation as observed in many H_2 bands In conjunction with the quantitative intensity measurements of Ornstein and his students it enabled us to ascribe to the H nucleus a spin of $\frac{1}{2}$ and to make sure that it obeys the Dirac Fermi statistics This latter result, together with the explicit knowledge of the rotational levels of H_2 as gained from analysis of the spectrum, again made acute the problem of interpreting the behaviour of the specific heat of hydrogen at low temperatures After Dennison had shown that this behaviour can be explained by considering the gas as a mixture of molecules in even and odd rotational states, which in general will not be in thermodynamic equilibrium, it was only a short time before other workers demonstrated this experimentally by separating the two components, para and orthohydrogen

The book under review is a monument to the co-operation between theory and experiment All physicists will be obliged to its author and to the Silliman Foundation for making the results of researches scattered in many different publications available in this compact and well produced book

R DE L KRONIG

The Thermionic Tube

(1) *Theory of Thermionic Vacuum Tubes Fundamentals, Amplifiers, Detectors* By Prof E Leon Chaffee (Electrical Engineering Texts) Pp xxiii+652+6 plates (New York McGraw Hill Book Co, Inc, London McGraw Hill Publishing Co Ltd, 1933) 36*s* net

(2) *Electron Tubes and their Application* By Prof John H Morecroft Pp xiii+458 (New York John Wiley and Sons Inc, London Chapman and Hall, Ltd, 1933) 28*s* net

(3) *Lehrbuch der Elektronen Rohren und ihrer technischen Anwendungen* Von Prof Dr H Barkhausen Band 2 *Verstarker* Vierte, vollstandig umgearbeitete Auflage Pp xvi+289 (Leipzig S Hirzel, 1933) 7 50 gold marks

(1) THE author warns us that this imposing volume is, 'according to present plans", the first of two, the second, to deal with power amplifiers and oscillators, gas content tubes rectifiers &c', can scarcely fail to reach a comparable size This probable development to some thirteen hundred pages is not an exaggerated measure of the progress made in the theory and practice of thermionic tube technique since 1920, when the classical volume of van der Bijl could be compressed into 390 open pages Van der Bijl's book was then unique, invaluable, indispensable, Chaffee's present work is its natural and worthy successor It contains nearly everything, within the limits indicated, that even the specialist is likely to require as a basis for his own work, and its list of references confirms the impression of encyclopædic completeness But ought it not to be labelled vol 1?

The book opens a little weakly, but gathers firmness of touch as it develops The introductory chapter, and the four-and a-half forbidding pages of symbols which precede it, have a flavour of pedantry and over elaboration which does less than justice to the author's handling of his main material The second chapter is also disappointing the rudiments of atomic theory are treated at unnecessary length, while Planck s constant suddenly appears, with no introduction at all several pages before it is equally summarily dismissed in three inadequate lines

At this point, however, the author reaches the real business in hand, and the temporary reversion to laborious systematisation in a brief chapter on nomenclature and letter symbols has no permanent ill effect Incidentally, however, this chapter itself indicates the solution for the admitted difficulties of symbolisation, for it shows how easily the inconvenient and inconveniently situated list of symbols, already mentioned, could have been compressed into a single page on a final throw out' sheet to unfold clear of the text or, less satisfactorily inserted in an end pocket The change would afford an opportunity for inserting some missing symbols The task of many readers might too, have been lightened by the freer use of a device, adopted in places by the author, of marking with an asterisk matter which may be omitted at a first general reading

Minor defects are not difficult to find but they are rare in proportion to the monumental scope of the treatise, and such as have been discovered will do no harm to any reader capable of using the book as it deserves to be used That Eccles should not be named or credited with the invention of the extremely convenient and now universal nomenclature of "diode, triode pentode ' (which the author uses throughout) might be excused were Richardson not, rather unnecessarily, mentioned as inventor of the substantive "thermion" (which the author immediately rejects) There is no mention of Round s signal service in bringing to practical application the screen grid tube, which Hull and Williams, in the paper cited by the author (and to which he gives considerable and deserved credit) left with the disclaimer "It will be understood that the purpose of this paper is scientific, and bears no relation to commercial development Tubes of the type described are not being manufactured, nor is their immediate production contemplated, so far as the authors are aware " Round's work in this connexion gives him a less qualified claim to a place in the name index than the one actually admitted

No serious reader will believe the author when he seems to assert that amplifiers and relays are one and the same kind of thing or when he seems to say that a modulator tube should be identical with an oscillator tube, or when he seems to say that slow electrons are less easily deflected by a magnetic field than are fast electrons Nor will Brucke ' for Brüche ' break down the bridge between the reader and the original paper on Experimente zu Stormers Polarlichttheorie" More serious than any of these lapses, perhaps, is the failure to quote, in the appropriate place on page 398, the important device of adding decoupling resistances to battery circuits common to several stages of an amplifier This process, which some of us in affectionate gratitude call 'Ferranti-ising avoids the difficulty, which affects also the circumstances discussed on page 456, of providing condensers of sufficiently low impedance at low frequencies to make an effective shunt across such low resistances as are presented by accumulators and filaments

There is evidence of the inclusion of much original work in addition to the systematic retreatment of the work of others The discussion of the overall characteristics and behaviour of the complete system of tube and associated circuits including the very important problems of input and output impedance and of equivalent circuits, deserves special mention The book is very complete and it has no present rival

(2) Prof Morecroft shares with Prof Chaffee a certain shakiness of hand when he takes up his pen for chap 1, but he too makes a quick recovery That the easy bits are the most difficult to write is no new discovery, but these erudite writers really ought to submit the manuscript of their first chapters to their youngest students for approval A salutary change between the things said at too great length and those left out would result

It is not at all a destructive criticism to say that Morecroft s work is more slender and superficial than Chaffee's These are, indeed, its essential merits, and it will do much to stimulate the best of its readers to go on to Chaffee, vol 1, and to fill the temporary void left by the absence of Chaffee, vol 2 The stimulation is not notably helped by the classical 'carrot and donkey' method of which the author is over fond, both in the fine structure, where the reader first feels that he has been left with an inadequate treatment, and then discovers that his troubles are cleared up two pages or so later, and in the main plan, where the uses of the principal devices are relegated to chapters much later than those in which the devices are introduced and described The irritated 'donkey' may kick over the traces before he is assuaged by the deferred 'carrot'

The book gives an excellently up to-date survey of the whole field, generously interpreted to include not merely the devices which the English reader *will* go on calling 'valves , but also photoelectric cells, cathode ray oscillographs the many recent gas and vapour filled tubes, and even thermocouples The young engineer entering industry from the technical school, to whom the work is addressed, will be a dull 'donkey' indeed if he is not fired to enthusiasm by the author Heat shielded cathodes giving emission currents of 1 5 ampere per watt of heating supply, ultramicrometers measuring deflections of a few atomic diameters, thermionic ammeters measuring currents of six electrons per second, and photoelectric eyes which can see fourteenth magnitude stars, are very succulent carrots' indeed

(3) Prof Barkhausen's classical work, in three volumes, is now passing through its fourth edition Vol 1 on general principles appeared in 1931, vol 2 on amplifiers is now before us, vol 3 on receivers is in preparation all having been rewritten A work by Prof Barkhausen, a work which has survived to a fourth edition, and a work thus brought up to date needs no discussion it has commended itself

Morphogenesis in the Animal Embryo

The Elements of Experimental Embryology By Julian S Huxley and Dr G R de Beer (Cambridge Comparative Physiology) Pp xiii+514 (Cambridge At the University Press, 1934) 25*s* net

THIS work is a rather surprising addition to the Cambridge Comparative Physiology series—surprising partly because it is twice as heavy as any of the earlier members of the series, and partly because it deals with what may perhaps be called one of the backward branches of biological science While the analysis of animal chemistry and animal energetics advances very rapidly in precision, the analysis of animal morphogenesis lags far behind If, for example, we turn to the study of animal behaviour, we find the observable phenomena described in terms of (*a*) the physico chemical properties of nerve cells and (*b*) the manner in which the cells are arranged in the nervous system , and while our understanding of the facts of the first group—of such processes as nervous conduction, excitation, inhibition and so forth—is rapidly advancing and increases almost literally from day to day, we know relatively little of the processes which have led the neurones to assume the patterns in which in fact they lie, and which determine, equally with their physico chemical properties, the reactions which the organism will give in any given circumstances The reason for this discrepancy is not far to seek Physiological analysis depends very greatly, for its ideas and methods, on physics and chemistry and in these sciences the emphasis has lain on quantities rather than on shapes

The authors of the volume under review are fully alive to this difficulty They have not attempted to review in their book all that is known about morphogenesis, but restrict themselves to what Wilhelm Roux termed the pre functional stage of development, that is, to the stage which begins with an undifferentiated, or relatively undifferentiated, egg, and ends with an embryo in which the main organs are laid down and the tissues histologically differentiated, adding only a brief chapter on the effects of function, both on the organ which functions and on other organs Moreover, they have restricted themselves in another way They do not attempt to analyse the processes involved in terms of physics and chemistry In their view, the field is not yet ripe for that harvest They work on what they term "the biological level ' To quote their preface

> The prime aim of the worker approaching the problem on the physiological level will always be to analyse the processes involved in terms of physics and chemistry The worker on the biological level will aim at discovering general rules and laws which he is content to leave to his physiological colleague for future analysis in more fundamental terms, but which, meanwhile, will give coherence and a first degree of scientific explanation to his facts Both methods are necessary for progress and while most biologists hope and expect that one day their laws will, thanks to the labours of their physiological colleagues, be made comprehensible in the most fundamental physico-chemical terms, they can reflect that it is they who must first reveal the existence of these laws before the physiologist can hope to begin his analysis "

In pursuing this aim, the authors have amassed and classified a vast amount of very entertaining facts Their method is to take as type the development of the amphibian embryo, on which of recent years a large amount of important work has been done, and then to turn to other animals to see how far the conclusions reached in connexion with frog and newt eggs can be usefully extended and generalised At first sight their volume contains more anecdote than law—it is a fascinating and exciting browsing ground—but as one reads there does emerge a framework of general principle a series of fundamental biological facts for the physiologist to explain Let us hope that he will read this volume and take up the challenge

As one expects from the authors the book is thoroughly up to date, and, by gathering together a great amount of work along different lines brings out suggestive relationships and generalisations There is an excellent bibliography, and important work that appeared after the book was in page proof is summarised in an appendix Occasionally criticisms suggest themselves, especially when the authors veer towards the physiological level For example, in discussing the development of pigment cells in the fish *Lebistes* they write "Specimens reared on white backgrounds have contracted melanophores, few in number, specimens reared on dark background have expanded melanophores in large numbers Functional activity increases rate of multiplication" There is, of course, no reason to suppose that an expanded melanophore is more "functionally active" than a contracted one The evidence collected to suggest that minute differences in oxygen supply between the ends of egg cells is a factor in determining polarity is perhaps unconvincing in the light of recent investigations on the shape of the curve relating oxygen tension to oxidation rate in single cells These are however, small points and in collecting this great array of fact and subjecting it to a preliminary regimentation the authors have, it is hoped, greatly assisted and accelerated the ultimate analysis to which they look forward

G P W

Short Reviews

Board of Education Science Museum *Handbook of the Collections illustrating Aeronautics* 2 *Lighter than Air Craft, a Brief Outline of the History and Development of the Balloon and the Airship, with reference to the National Aeronautical Collection, and a Catalogue of the Exhibits* By M J B Davy Pp 112+32 plates (London H M Stationery Office, 1934) 2*s* 6*d* net

MR DAVY, the officer in charge of the Aeronautical Collection at the Science Museum, South Kensington, has, with the issue of this book, completed a series of three, which constitutes a very completely annotated catalogue to the collection of aeronautical exhibits at that Museum, in addition to providing a concise and useful history of aeronautics in Great Britain The companion volumes already issued, are vol 1 "Heavier than air Craft and vol 3 "Propulsion of Aircraft

These books are astonishingly full of meat presented in an orderly and readable manner, and read in conjunction with visits to the collection cannot fail to educate visitors in the part that Great Britain has played in the development of the science of mechanical flight, a history which is all too little known or appreciated It is a pity that in a few instances the author does not stick to the definitions laid down in the "British Standard Glossary of Aeronautical Terms" Many of these are admittedly subjects of controversy, but confusion of terms can only be removed by strict loyalty to the agreed authorities in the matter For example chap v is headed Pressure Type Air ships ' This term was deliberately omitted from the British Standard Glossary in favour of the two sub divisions non rigid and semi rigid airships

The book is divided into chapters dealing with the early speculations as to lighter than air flight , hot air balloons , spherical hydrogen balloons , early dirigible balloons or airships , non rigid and semi rigid airships, and rigid airships It covers a period from Roger Bacon (1214) to a reference to the *Akron* disaster in the U S A (1933) The illustrations are particularly good, and add considerably to the usefulness of the volume

The Ape and the Child a Study of Environmental Influence upon Early Behavior By Prof W N Kellogg and L A Kellogg (Whittelsey House Publication) Pp xiv+341+33 plates (New York Mc Graw Hill Book Co , Inc , London McGraw Hill Publishing Co , Ltd , 1933) 12*s* 6*d* net

IF a baby ape were brought up in human surroundings and treated like a human child, how far would it acquire human characteristics ? This is one of the problems Prof and Mrs Kellogg have tried to solve in the unique experiment related in this book Gua, a female chimpanzee, was reft from her mother at the tender age of 7½ months, and brought up in the Kellogg household with their son Donald, who was 2½ months older They lived together as companions and playmates for nine months, being treated in every way as nearly as possible alike, and they became great friends A very detailed study was made of their sensory and motor capacities, their power of learning, their rate of maturation The little ape showed herself surprisingly intelligent, though not quite up to the level of the child in some respects, as in muscular strength and co ordination, she was the child's superior, due in part to her more rapid rate of development Simple things she learned more rapidly than the child, probably for the same reason

A detailed comparison with the behaviour of an ape brought up in the normal way is unfortunately not given, but it is clear that Gua was considerably affected and stimulated to higher flights by her new and exciting psychological environment 'It is clearly in defence of the capacities of the animal that the results of the present research are most significant They strongly suggest that, if given sufficient opportunity, the animal subject may considerably outdo himself, particularly if he belongs at a high level in the biological scale (p 322) There is a vast amount of useful material in the book for the student of child and anthropoid psychology

E S R

A Text Book of Inorganic Chemistry Edited by Dr J Newton Friend (Griffin's Scientific Text Books) Vol 6, Part 2 *Phosphorus* By Dr Edmund B R Prideaux Pp xxviii+238 (London Charles Griffin and Co, Ltd, 1934) 18*s* net

THE part of Friend s Text Book of Inorganic Chemistry" which deals with phosphorus and its compounds has been written by Dr Prideaux on similar lines to those in which the other elements have been described, and maintains the characteristic features of the series This statement implies that the book is traditional rather than modern in its methods and outlook, and is therefore of more value as an index to the published literature than as a stimulant to research in its broader aspects Since Dr Prideaux is keenly interested in problems of valency, in reference to which he has himself made original contributions, it is an anomaly (for which the editor is perhaps responsible) that, although data are cited for the parachor of phosphorus oxychloride, no reference is made to their interpretation by means of a semi-polar bond, and that when, in certain rare instances, structural formulæ of compounds of this type are set out in full, the atom of phosphorus is associated with five bonds

The book may therefore be commended without reserve to those who wish to study fundamental chemistry, undefiled by any taint of modernism, but it will disappoint those who may consider that the problems of molecule building are too important to be discussed adequately in three paragraphs of less than half a page each in a book of more than 200 pages

Handbuch der Chemotherapie Von Dr Viktor Fischl und Prof Dr Hans Schlossberger Teil 2 *Metallderivate* Pp xi+359–898 (Leipzig Fischers medizinische Buchhandlung, 1934) 55 gold marks

THIS second volume completes the work (the first volume of which was reviewed in NATURE, 132 694 1933) and is provided with an adequate index covering the contents of the two volumes The issue of a third volume comprising a general section on theories of chemotherapy has been postponed with the laudable object of preventing the book from becoming at once too bulky and too costly The projected third volume will either appear as an independent work or be added if and when a new edition is required

The metallic derivatives (including those of fluorine and iodine) are treated on the same plan and with the same clarity and precision as the metal free organic compounds in vol 1 Of special value are the introductory historical surveys of the therapeutic use of each element

One third of the book is devoted to arsenic compounds, of which there is a very full account Incidentally, the Styrian arsenic eaters are said to have taken the trisulphide whereas it is generally understood that they consumed the oxide Special sections are devoted to the compounds of antimony bismuth, copper, silver, gold, mercury and the rare metals

The work forms a valuable addition to the literature of the subject, and the authors are to be congratulated on its speedy completion

The African To day By Prof Diedrich Westermann (Published for the International Institute of African Languages and Cultures) Pp xv+343 (London Oxford University Press, 1934) 7*s* 6*d* net

THOSE who wish to know something of present day conditions in native Africa and to understand why and how things have come to be as they are, may take up this book with confidence that what is essential will be found in its pages and for the most part told at first hand Dr Westermann explains the ethnic composition of the African peoples, their linguistic affinities, and demonstrates the constituents of their culture In the case of the last named, taking each aspect in turn, religion, social organisation, economics, material culture and the like, he shows how they have come into contact with European civilisation, the resulting modification in each instance, and its effect on native life generally Tendencies and possibilities are carefully considered

The book should be read in conjunction with the scheme for African research of the International Institute of African Languages and Cultures, more familiarly known as the 'Five Year Plan', to which indeed Dr Westermann makes frequent reference The prolegomena to that plan and Dr Westermann's book give a plain statement of facts, which should not be ignored in the future political and economic policy of Africa

Surface Tension*

By Dr. Allan Ferguson

OUR subject is very closely associated with the comprehensive topic of cohesion, a topic which attempts an answer—not to the problem *why* we are here to-night, which is a matter for the theologians to discuss—but the problem, *how* we are here, in our present habits, and not as a chance medley of unattracting atoms. To attempt to answer such a query takes us very far towards the fundamentals of atomic structure and behaviour, but the problem, as we envisage it in the light of to-day's theories, still bears a strong resemblance to the problem as it was posed and answered, by van der Waals. How comes it that, if material particles attract each other the whole structure of the universe does not collapse under these attractions? We can formulate an answer to the question if we take into account the thermal motions of the particles. "In nature it is cohesion between atoms which tends to produce condensation and solidification and temperature which tends to produce dissociation. Temperature is a manifestation of kinetic energy and cohesion of potential energy and the interplay of these two forms of energy is responsible for many of the observed physical properties of matter" (Lennard-Jones). Cohesion and temperature—these, then, are the protagonists who play out the drama.

The main change of view during the last generation depends on the change which has taken place in our concept of the ultimate material particle and the structure of the atom. The billiard ball atom of the nineteenth century physicist served its purpose well, and subserves a useful function to-day. It is not surprising that so naïve an extrapolation of our large scale processes should ultimately break down—the surprising matter is that the extrapolation should have proved so brilliantly successful as it has done. Such a type of atom was assumed to have a definite size, and this notion of clear-cut dimensions was not lost when it was found that the concept was not fine grained enough to interpret successfully radioactive phenomena, and the nuclear atom displaced it. Here the concept of size was associated with the dimensions of the electronic orbits and, though the atom became a far more complex system, there was no haziness about the notion, apart from the difficulty of an exact determination of its dimensions.

We have changed all that to-day. We cannot hope to locate our electrons precisely and the definite orbit of the electron of the nuclear atom is now replaced by a *probability pattern*, the density of the pattern at any point measuring the probability of finding an electron there. Fortunately, the uncertainty which we have introduced into our concepts has not seriously altered our views concerning the order of atomic magnitudes, inasmuch as the probability of finding an electron in any particular pattern becomes infinitesimal outside regions of the magnitude of about one hundred millionth of a centimetre. We may still, therefore, keep to an interpretation of the size of an atom which, despite a little cloudiness at the edges, does not differ materially from the interpretation based on the older concepts.

What are, then, the dimensions of the atoms and molecules with which we have to deal? Any example that we may give to illustrate the meaning of such atomic magnitudes merely transforms an inconceivably small number into an inconceivably large one; let it suffice to say that if we could curb the liveliness of the hydrogen atoms and lay them in order on a sixpence, it would take some eight hundred million years of unceasing work to cover the coin, if we laid our atomic bricks at the rate of one a second.

We shall, therefore picture a liquid as a congeries of such particles in lively thermal motion, attracting and being attracted according to a law which we need not attempt to specify more closely than by saying that the attraction of any one molecule on its neighbours falls off very rapidly as the distance increases. If then we draw round any one molecule well in the interior of the liquid, a small sphere the radius of which we may term the range of molecular attraction, the central molecule will experience no resultant force due to the attractions upon it of its neighbours within this sphere.

It is otherwise if the central molecule is at a distance from the surface of the liquid which is less than the radius of this sphere. Part of the sphere is now outside the liquid, the molecules therein are missing, and do not contribute their share to the force on the molecule at the centre of the sphere, which molecule therefore experiences a force urging it into the liquid. To transport a molecule from the interior of the liquid into the liquid surface against such a force requires, therefore, the expenditure of *work*; and inasmuch as the conveyance of molecules into the surface means an extension of the surface, to extend a liquid surface necessitates the expenditure of work. Stretch a sheet of rubber, and notice that we have to do work to extend the rubber surface.

We must not press simple analogies too far, but it is legitimate to assume that the surface of a liquid behaves as if it were in a state of tension, and the tension in the surface across a line of unit length drawn in the surface is called the *surface tension* of the liquid. We may demonstrate its existence by forming a soap film on a circle of copper across which a loose thread of cotton has been tied. Destroy the film on one side of the thread, and the thread is pulled by the tension of the film on the other side into a very perfect arc of a circle. This tension differs for different substances, as we may show by pouring a little alcohol on to a thin film of coloured water at the bottom of a glass dish, and noting how a clear space is formed in the middle of the dish where the alcohol —the liquid of weaker tension—was poured in

---

* From a Friday evening discourse delivered at the Royal Institution on February 16.

For any one liquid, the tension decreases with increasing temperature We may show this by scattering lycopodium on the surface of water in a dish, and bringing a heated bit over the centre of the dish The greater tension of the cold water is clearly shown by the way in which the central space is swept clear of the powder Following Lord Kelvin's dictum that we know something about a quantity when we can make measurements thereon, it may not be amiss to state that the law connecting surface tension (γ) with temperature (θ) is $\gamma=\gamma_0(1-b\theta)^n$, where b is very accurately the reciprocal of the critical temperature, and n, which varies only slightly from liquid to liquid, may be assumed to have a mean value of 1·2 This relation holds good for *unassociated* liquids A film of oil covering a thin rod breaks up into a series of regularly spaced drops, illustrating the instability of a liquid cylinder the length of which exceeds its circumference A similar result may be illustrated for a liquid annulus by cutting a narrow circular groove on the lower surface of an iron disk, placing the disk on a horizontal glass plate and filling the groove with mercury On lifting the disk, the ring of mercury breaks up at once into a series of regularly spaced drops

These drops take on an approximately spherical form, and the tendency to sphericity becomes more pronounced as the drops become smaller, and those forces, such as the weight of the drop, become increasingly unimportant in comparison with the surface forces A spherical surface is that surface which, for a given volume, has a minimum area, and this tendency to the exposure of the smallest possible extent of surface illustrates the principle that a dynamical system tends to take up a position in which its potential energy is a minimum

Another experiment we owe to the ingenuity of Major C E S Phillips Two light vertical rods serve as supports To the top of one is fixed a *circular* microscope cover slip with its plane horizontal, the other support carries a horizontal *square* cover slip Two other slips, one square, one circular, carry fastened to their upper surfaces long and light straw pointers Lay these on the top of the fixed slips, and, clearly, you can spin them round as you will But now place a drop of water between each of the pairs of slips, and endeavour to revolve the upper movable slips The circular one moves freely over its circular fellow and remains with its pointer pointing in any direction which you choose to give to it Displace the square one, and it snaps back into a perfectly definite position of equilibrium in which the upper slip is exactly congruent with the lower It is a delightful experiment, and one is tempted to say of it, *mutatis mutandis*, what Praed said of the Vicar's sermons

These few fundamental principles, consistently applied, will serve to elucidate a great many problems in which surface energy plays a dominant part

But we must hasten to the second part of the discourse, which is concerned with a very commonplace phenomenon—that of the detachment of a drop of liquid from a vertical tube Study the process at any slowly dripping tap, and you will see that, although the initial stages may very easily be examined, the final stages of detachment occur with a rapidity which makes it impossible for the eye to follow them How may we slow the process ? Aniline and water are almost immiscible, and the density of aniline is but slightly greater than that of water If, therefore we form an aniline drop at the end of a vertical tube dipping into water, we may project the image of the drop on to a screen, and study the circumstances of its detachment with much greater ease

Pitch is a queer substance to forces of short duration it behaves as a solid, leave it to itself and it will flow like a liquid Pitch in a funnel gives a very perfect drop of pitch pendent from the stem of the funnel It seems static enough but although it flows, like Cæsar's Arar, *incredibili lenitate*, nevertheless it *does* flow, as a few months inspection would show

Yet another way in which we can slow down the process A sheet of indiarubber is stretched tambourine fashion, across a circular frame, and held in position by a serving of cord and a tourniquet If water is slowly run into the tambourine, the rubber first assumes a lenticular form and then takes on a position of equilibrium in which a pronounced waist is seen in the profile of the drop This position, impossible as an equilibrium position in a water drop is possible here because the tension in a rubber surface increases with the extension, whereas the tension in a liquid surface is, under conditions of constant temperature, independent of the extent of the surface This experiment was shown by Lord Kelvin at the Royal Institution in his Friday evening discourse of January 29, 1886 If his biographer ("Life of Lord Kelvin", p 854, vol 2) is a veracious chronicler the growth of the drop "furnished an exciting episode in the lecture, which culminated when finally the elastic film gave way and the drop burst over the lecture table, splashing the nearer members of the fashionably attired audience"

Even in 1886, it was possible to take an instantaneous photograph of the detachment of a drop of ink from a funnel, to-day the progress of high-speed kinematography has made it possible to follow the details of the process with the camera A high speed camera, developed in the Bell Telephone Laboratories in conjunction with the Eastman Kodak Company, makes it possible to take photographs at a normal rate of a thousand per second and, by overvolting the motor, we have been able to increase this rate to nearly two thousand per second. Obviously at these speeds the intermittent jerking of the film through the camera is impossible, and the film hurtles past the lens at a uniform speed of close on thirty miles an hour when the motor is overvolted. Between the lens system and the vertically descending film is a prism which can be rotated about a horizontal axis at a maximum speed of eighty thousand revolutions per minute, and this prism permits twice in each revolution of the passage of light from lens to film, and therefore exposes an image on the film for a period of the order of one five-thousandth of a second. There is no special difficulty in the illumination of the object, in all the experiments to be described a thousand watt lamp and a simple projector gave all the illumination necessary. A special feature of the camera is a two-dialled clock, one of the dials rotates once a minute and registers seconds; the other dial rotates once in a second and is graduated into five hundred divisions in such a way that thousandths of a second may be estimated. An auxiliary prism throws the images of these dials on the film, and the time relations of the phenomenon under observation may therefore be registered with very high accuracy.

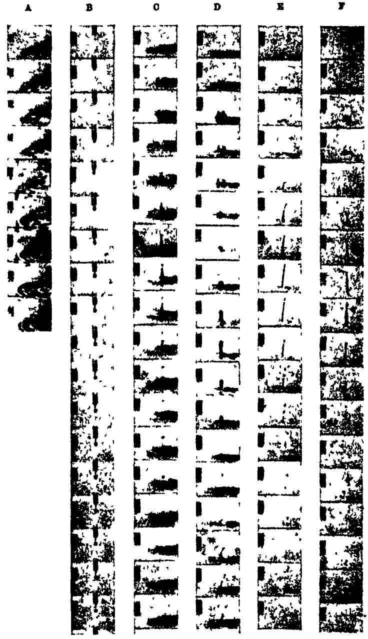

Fig 1

Readers of the fantasies of Mr. H G Wells will remember that delightful story in which the hero takes a drug which temporarily alters his time-scale of living. Under its influence he writes a three-hour article at what he presumes is his normal rate; when the effect of the drug has worn off he finds that he has accomplished his task in a few minutes. He takes a walk, and notices a bee flapping its wings lazily in the wind, he accelerates his speed, and is brought up by a smell of burning—the rapidity of his motion through the air has caused his trousers to singe.

Suppose, then, we make an attempt to enter a world the time scale of which is such that we can study the manner in which a drop detaches itself from a tap—we can do this by running a film taken by the high-speed camera through the projector at a rate of fifteen or twenty pictures a second. We have altered our time scale in the ratio of about a hundred to one. In this way (Fig. 1, B) all the stages of the detachment of a drop, and the lenticular form, the waist formation, the drawing-out of a long neck and the final detachment of the drop and its accompanying satellite can be followed with the greatest ease.

But the most interesting application of kinematography of this type which I have as yet been able to make, is the study of the beautiful phenomena described some thirty or forty years ago by Prof. A M. Worthington, who photographed the splash of a drop of liquid into liquid, of a solid sphere into a liquid, and of a liquid drop falling on to a solid plate ("A Study of Splashes", 1908). That something odd happens when, *ex gr.*, a drop of water falls on a smoked glass plate is well seen on these slides, the radial striations on which show that the drop has been throwing out arms in what, at first sight, seems a very queer fashion.

Worthington investigated the phenomenon by taking an instantaneous photograph of, say, a drop of water falling into milk at a certain stage of its fall and then, by an ingenious timing device, ensured that a second drop, released under conditions identical with those of the first drop, should be illuminated instantaneously at a stage of its fall one five hundredth of a second later than that stage at which its predecessor was illuminated, and so on. Worthington, in fact, took photographs of different drops at varying stages of their careers and from the photographs pieced together the life history of a single drop. The high speed camera enables us to do this directly, and frees us from certain obvious complexities introduced by the varying behaviour of different drops—complexities which, on occasion, proved very puzzling to Worthington.

The film (Fig. 1 A) which shows the splash of a water drop into water is not perhaps so spectacular as some of the others but it has a mild historical interest inasmuch as it is, I think, the first film to show the phenomenon, and it was actually our first film, taken with no special precautions as regards stopping of the lens and illumination. Addition of a little milk to the water brings out the detail, and it is most interesting to note how closely the story follows that unfolded by Worthington's pictures. We see the effect of a low fall, about 40 centimetres (Fig. 1, C) and of a high fall, about a metre (Fig. 1, D), the high fall showing very beautifully the stages in the process of bubble formation on the surface of the liquid. In Fig. 1, E and F, are shown the effects of a low and of a high fall due to an ordinary rough marble sphere falling into a liquid. The whole story of these events is told in something of the order of half a second, and the slow motion projection enables us to multiply this period by a factor of about a hundred.

The splash of a drop of mercury on a glass plate is a little more difficult to follow—it is over in about a twentieth of a second, and even the high speed camera is not quick enough to enable us to grasp the complete detail. Nevertheless, we hope to be able to speed up the camera still further, and this gain of speed, with the aid of the technique of the photographer, may make it possible to show to an audience even so evanescent a phenomenon as this.

Germination of Seeds*

By Sir Arthur W. Hill, K.C.M.G., F.R.S.

We may now consider those seeds which on germination escape from their endocarps or stones by throwing off a specially prepared portion only of the endocarp wall. The best examples of such fruits, enclosing a single seed, are afforded by the tupelos, *Nyssa*, and by *Mastixia*, both belonging to the family Cornaceæ. The valve, which is thrown off on germination, which may be compared to the shutter of a shop front, is about one third the length of the stone, square cut at the base, with a bluntly triangular apex. Until germination commences it is scarcely possible to see the outline of the valve, since the surface markings of the stone are continuous over the valve and the rest of the fruit. When germination commences and the substance cementing the valve to the rest of the endocarp is dissolved, the radicle pushes off the shutter, which becomes completely detached, and so the embryo effects its escape. It is of interest to notice that specimens of fossil seeds of *Nyssa* and *Mastixia*, found in Eocene beds in the Isle of Wight and in Pliocene beds of the Dutch Prussian frontier, show the valve structure perfectly. There is a further interest in these fossil seeds, since *Nyssa* to day is only known in the eastern United States, the Himalayas and the Malayan Islands, and *Mastixia* in India and the East Indies.

The cornels, *Cornus*, have fruits of a similar character, but differ in having two seeds enclosed in an endocarp, which necessitates the splitting off of two shutters, one for each embryo, when germination commences. As in *Nyssa*, the shutter has a horizontal base and before germination takes place the presence of the valves or shutters cannot be detected.

The fruit of *Canarium* (Burseraceæ) contains three seeds enclosed in a stony endocarp. The hard woody valves or shutters are triangular ovate, pointed at the apex and horizontal at the base, and are about two thirds the length of the stone. On the inside they are concave. The seed cavity is the full length of the stone and the radicle of the embryo is at its broader upper end. On germination, the radicle pushes the shutter upwards and the arch of the hypocotyl raises the shutter still more. The embryo, however, is well surrounded by its seed coats and in order to extract its cotyledons properly a peg like structure is developed at the apex of the radicle on the seed side, which grows over the lower edge of the stone much as in the vegetable marrow. The young seedling thus treads on the floor of its prison box, keeping it firmly on the soil, while the hypocotyl, exerting its full pressure, withdraws the cotyledons both from their own seed coats and from their wooden, box like prison.

The seeds of the teak tree (*Tectona grandis*, Verbenaceæ) show a similar arrangement of shutters. Here, however, there are four cavities in the endocarp and the four shutters extend nearly the whole length of the stone. When the shutters are thrown off on germination the destruction of the prison has been so complete that only the partition walls remain. *Saccoglottis* and *Aubrya* (Humiriaceæ) may be mentioned in passing, since in them five embryos may be incarcerated, each in its separate cell. They too escape by taking down the shutters.

---

* *Continued from p.* 859

Davidia, another of the Cornaceæ, a remarkable Chinese tree introduced to cultivation a few years ago—which, when in flower, resembles a large wash of white pocket handkerchiefs hung out to dry—has the most complicated of the shutter devices for imprisoning or safeguarding the seeds. In this plant seven or more seeds may be contained in each stony endocarp and, as they lie close together, only one seedling is likely to survive owing to overcrowding, since they cannot get away from their fellows. The protection for the embryos is admirable, but almost over ingenious, since the object in view, the propagation of the species, is somewhat defeated when so many good seedlings must eventually perish. This almost suggests a 'slum' analogy! The hard stony endocarp of *Davidia* is deeply fissured and when ripe no trace of the shutter-like valves can be seen. The shutters, however, as a cross section shows, are all prepared and ready to be loosened when the opportunity comes. The shutters are similar to those already described—some two thirds the length of the stone, long, narrow and thick, and hollowed on the inside. On germination not only is the shutter thrown off, but also a portion of the endocarp wall or rib between each shutter is shed, and this portion, no doubt, serves to cement the seeds or ovules all the more securely and hermetically in their narrow cells. As I have already mentioned, however, many of the escaped prisoners die of starvation due to overcrowding, since they are unable to move away from the neighbourhood of their former prison.

I must now direct attention to a somewhat different method of imprisonment by means of cork like stoppers and lids. The fruit of the mare's tail, *Hippuris*, a well known British water plant, contains a single seed, and the endocarp, which in this case is not hard and stony, is shaped like an ovoid bottle and corked at the neck by a plug or stopper of hardened tissue. It may be compared to a test tube plugged with a stopper of cotton wool. On germination, the radicle of the embryo within the cavity or tube forces out the stopper, like the ejection of a champagne cork, and so effects its escape.

The large, woody, spherical fruits of *Northea seychellana* (Sapotaceæ) shew a small circular area at one end, which proves to be a cap fitting into and closing an orifice, beneath which lies the radicle of the embryo. This cap is pushed off on germination and the shoot apex is pulled out into freedom through the orifice by the lengthening of the stalks of the cotyledons which, themselves, remain within the seed.

It is when we come to examine the fruits of various members of the Anacardiaceæ, the family to which the cashew nut, mango, pistachio nut and other edible fruits belong, that we find some remarkable contrivances for the protection of the seeds, and equally ingenious devices by which they make their escape on germination.

Hæmatostaphis, the blood plum of Nigeria, is an example of a stony endocarp with a lid containing a single seed. On removal of the flesh of the fruit a small lid like structure can be seen at the apex of the stone, which forms a close fitting stopper, hermetically sealing the orifice of the cavity in the endocarp in which lies the embryo with its radicle directly under the lid. On germination the lid separates into two halves, like a pair of doors which are pushed aside by the emerging radicle. Before germination there is no indication that the lid is a double structure which can be thrown open for the exit of a visitor, like front doors of a millionaire's mansion!

The Kaffir plum of South Africa, *Sclerocarya caffra* and *Dracontomelon* from the East show similar devices to *Hæmatostaphis*, except that in the former, three, and in the latter five, embryos are enclosed in each stony endocarp. The cavities containing the seeds or embryos are in each case closed with a cap like lid, in shape like a circular military cap, some 3 mm. thick, hollowed out on the inner side and thinned out at the lower corner. This is the weak spot in the armature through which external moisture can enter when the fruits are sown, and it is also the spot at which the embryo makes its attempt at escape by pushing up the cap with its developing radicle.

During the War some fruits were picked up in the East end of London, after an air raid; they were sent by the Home Office to the Pharmaceutical Society for examination and thence to Kew for determination, as it was thought they had been dropped from an enemy aeroplane with sinister purpose, since they were succulent and edible. The fruits proved to be those of *Dracontomelon sinense* and had no doubt been dropped by some sailor home from the East!

A yet more elaborate and complicated device remains to be described in this same family *Anacardiaceæ*, which has been evolved in the genus *Pleiogynium*, the Burdekin plum of Queensland, Australia. Here the seeds are not only enclosed in stony endocarps, but also to ensure more complete protection of the embryo, the middle portion of the fruit—the mesocarp—has become stony, and the stony endocarps are, in addition, surrounded and enclosed in an outer, woody box, like the proverbial pessimist who considers it essential to wear braces in addition to a belt! Here, again, the protection seems to have somewhat overshot the mark; for some twelve seeds are imprisoned in this outer turbinate, woody box (2·8 cm. in diameter), and ultimately, on germination, only one of the seedlings is likely to survive in the competition with its close neighbours.

Each stony endocarp in this enclosing box has a lower tubular portion more or less fused with the tissues of the mesocarp, and an upper cap-like portion firmly cemented to the lower part, which becomes detached on germination and is pushed through the orifice in the mesocarp so that the embryo can emerge The caps are somewhat similar to those of *Sclerocarya* and *Dracontomelon*, but they are triangular in section and hollowed within to contain the upper part of the embryo In shape they resemble a French forage cap

The extreme case of wastage of effort is that of the Brazil nut, *Bertholletia* When you purchase Brazil nuts, you rarely, if ever, see the fruit body in which they are contained The well known 'nuts' are the seeds with their strong, woody seed coat, but they are contained in a large, woody, spherical fruit some six inches in diameter, with a wall half an inch thick and as hard as well seasoned oak, with a smooth, glass-like inner layer At one end of the ball there is a small orifice firmly plugged by a stopper, and inside the 15–20 seeds are so neatly packed, with their thin edges inwards, that the hollow wooden sphere is completely filled, and no space is wasted When conditions are favourable for germination, the seeds inside all commence to germinate at once The orifice, half-an inch across, however, is their only means of escape, as the fruit wall remains hard and intact The result may be compared with the rush of a crowd on the call of "Fire" at a theatre Every one tries to get out at once and only one out of the 15–20 prisoners survives! Surely this is a case where the means have defeated the end

Tennyson may well have had the Brazil nut in mind when, referring to Nature, he wrote

> So careful of the type she seems,
> So careless of the single life,
>
> That I, considering everywhere
> Her secret meaning in her deeds,
> And finding that of fifty seeds
> She often brings but one to bear,
>
> I falter where I firmly trod,"

Why should some seeds, like those of many orchids and lilies, papery in their texture and almost transparent, survive perfectly well in a dormant condition for a long period, while others need a strong protective envelope?

All these questions relating to the nature of the life in a dormant seed, whether germination may be immediate or may be long delayed, and the ingenious methods of germination, afford problems of much interest, all the more so since they are so illusive and because our attempts to solve them are confronted by so many difficulties

Possible Production of Elements of Atomic Number Higher than 92

By PROF E FERMI, Royal University of Rome

UNTIL recently it was generally admitted that an atom resulting from artificial disintegration should normally correspond to a stable isotope M and Mme Joliot first found evidence that it is not necessarily so, in some cases the product atom may be radioactive with a measurable mean life, and go over to a stable form only after emission of a positron

The number of elements which can be activated either by the impact of an α particle (Joliot) or a proton (Cockcroft, Gilbert, Walton) or a deuton (Crane, Lauritsen, Henderson, Livingston, Lawrence) is necessarily limited by the fact that only light elements can be disintegrated, owing to the Coulomb repulsion

This limitation is not effective in the case of neutron bombardment The high efficiency of these particles in producing disintegrations compensates fairly for the weakness of available neutron sources as compared with α particle or proton sources As a matter of fact, it has been shown[1] that a large number of elements (47 out of 68 examined until now) of any atomic weight could be activated, using neutron sources consisting of a small glass tube filled with beryllium powder and radon up to 800 millicuries This source gives a yield of about one million neutrons per second

All the elements activated by this method with intensity large enough for a magnetic analysis of the sign of the charge of the emitted particles were found to give out only negative electrons This is theoretically understandable, as the absorption of the bombarding neutron produces an excess in the number of neutrons present inside the nucleus, a stable state is therefore reached generally through transformation of a neutron into a proton, which is connected to the emission of a β particle

In several cases it was possible to carry out a chemical separation of the β active element, following the usual technique of adding to the irradiated substance small amounts of the neighbouring elements Those elements are then separated by chemical analysis and separately checked for the β activity with a Geiger Müller counter The activity always followed completely a certain element, with which the active element could thus be identified

In three cases (aluminium, chlorine, cobalt) the active element formed by bombarding the element of atomic number Z has atomic number $Z - 2$ In four cases (phosphorus, sulphur, iron, zinc) the atomic number of the active product is $Z - 1$ In two cases (bromine, iodine) the active element is an isotope of the bombarded element

This evidence seems to show that three main processes are possible (*a*) capture of a neutron with instantaneous emission of an α particle; (*b*) capture of the neutron with emission of a proton, (c) capture of the neutron with emission of a γ-quantum, to get rid of the surplus energy From a theoretical point of view, the probability of processes (a) and (b) depends very largely on the energy of the emitted α or H-particle, the more so the higher the atomic weight of the element The probability of process (c) can be evaluated only very roughly in the present state of nuclear theory, nevertheless, it would appear to be smaller than the observed value by a factor 100 or 1,000

It seemed worth while to direct particular attention to the heavy radioactive elements thorium and uranium, as the general instability of nuclei in this range of atomic weight might give rise to successive transformations For this reason an investigation of these elements was undertaken by the writer in collaboration with F Rasetti and O D Agostino

Experiment showed that both elements previously freed of ordinary active impurities can be strongly activated by neutron bombardment The initial induced activity corresponded in our experiments to about 1,000 impulses per minute in a Geiger counter made of aluminium foil of 0 2 mm thickness The curves of decay of these activities show that the phenomenon is rather complex A rough survey of thorium activity showed in this element at least two periods

Better investigated is the case of uranium, the existence of periods of about 10 sec, 40 sec 13 min plus at least two more periods from 40 minutes to one day is well established The large uncertainty in the decay curves due to the statistical fluctuations makes it very difficult to establish whether these periods represent successive or alternative processes of disintegration

Attempts have been made to identify chemically the β active element with the period of 13 min The general scheme of this research consisted in adding to the irradiated substance (uranium nitrate in concentrated solution, purified of its decay products) such an amount of an ordinary β active element as to give some hundred impulses per minute on the counter Should it be possible to prove that the induced activity, recognisable by its characteristic period, can be chemically separated from the added activity, it is reasonable to assume that the two activities are not due to isotopes

The following reaction enables one to separate the 13 min product from most of the heaviest elements The irradiated uranium solution is diluted in 50 per cent nitric acid a small amount of a manganese salt is added and then the manganese is precipitated as dioxide (MnO_2) from the boiling solution by addition of sodium chlorate The manganese dioxide precipitate carries a large percentage of the activity

This reaction proves at once that the 13 min-activity is not isotopic with uranium For testing the possibility that it might be due to an element 90 (thorium) or 91 (palladium), we repeated the reaction at least ten times, adding an amount of uranium $X_1 + X_2$ corresponding to about 2,000 impulses per minute, also some cerium and lanthanum were added in order to sustain uranium X In these conditions the manganese reaction carried only the 13 min activity, no trace of the 2,000 impulses of uranium X_1 (period 24 days) was found in the precipitate, and none of uranium X_2, although the operation had been performed in less than two minutes from the precipitation of the manganese dioxide, so that several hundreds of impulses of uranium X_2 (period 75 sec) would have been easily recognisable

Similar evidence was obtained for excluding atomic numbers 88 (radium) and 89 (actinium) For this, mesothorium 1 and 2 were used, adding barium and lanthanum, the evidence was completely negative as in the former case The eventual precipitation of uranium X_1 and mesothorium 1 which do not emit β rays penetrating enough to be detectable in our counters would have been revealed by the subsequent formation respectively of uranium X_2 and mesothorium 2

Lastly we added to the irradiated uranium solution some inactive lead and bismuth, and proved that the conditions of the manganese dioxide reaction could be regulated in such a way as to obtain the precipitation of manganese dioxide with the 13 min activity without carrying down lead and bismuth

In this way it appears that we have excluded the possibility that the 13 min activity is due to isotopes of uranium (92), palladium (91), thorium (90), actinium (89) radium (88), bismuth (83), lead (82) Its behaviour excludes also ekacæsium (87) and emanation (86)

This negative evidence about the identity of the 13 min activity from a large number of heavy elements suggests the possibility that the atomic number of the element may be greater than 92 If it were an element 93, it would be chemically homologous with manganese and rhenium This hypothesis is supported to some extent also by the observed fact that the 13 min activity is carried down by a precipitate of rhenium sulphide insoluble in hydrochloric acid However, as several elements are easily precipitated in this form, this evidence cannot be considered as very strong

The possibility of an atomic number 94 or 95 is not easy to distinguish from the former, as the chemical properties are probably rather similar Valuable information on the processes involved could be gathered by an investigation of the possible emission of heavy particles A careful search for such heavy particles has not yet been carried out as they require for their observation that the active product should be in the form of a very thin layer It seems therefore at present premature to form any definite hypothesis on the chain of disintegrations involved

Obituary

SIR ROBERT CARLYLE, K C S I, C I E

ALTHOUGH even now natural science finds no place as a compulsory subject in the competitive examinations for the higher ranks of the public service, nevertheless the Indian Civil Service has often included in its ranks a few staunch supporters of the man of science In this select band the late Sir Robert Warrand Carlyle, a kinsman of the 'sage of Chelsea', whose death in his seventy fourth year occurred at Florence on May 23 last, takes an honoured place Four years ago he was seriously injured by a motor lorry in Essex, an accident which was followed by repeated attacks of pernicious anæmia which even his robust constitution could not long withstand

Educated at the University of Glasgow and Balliol College, Oxford, Carlyle passed the Indian Civil Service Examination in 1878 and was duly posted to Bengal In 1894 he reached the rank of magistrate and collector and served for many years in the District of Darbhangha, in which in 1904 Lord Curzon founded the Pusa Agricultural Research Institute After eight years service as a district officer he was called to headquarters at Calcutta, first as Inspector General of Police and then as Chief Secretary to the Government of Bengal

In 1907 Carlyle was selected for service under the Government of India as Secretary to the Department of Revenue and Agriculture and for the next three years came in the closest touch with most of the scientific workers employed by the Central Government, both administratively and also as chairman of the Board of Scientific Advice

With characteristic thoroughness, Carlyle applied himself to a close study of these somewhat unfamiliar activities, and also made a point of getting into personal touch with the workers themselves. In this latter task he was greatly assisted by Lady Carlyle, who took a deep personal interest in her husband's work and freely devoted her great social gifts to the entertainment of a constant stream of official visitors, many of whom were connected with some branch of science After three years' service as Secretary, Carlyle was promoted in 1910 to a seat in the Viceroy's Council, his charge including the Department of Revenue and Agriculture and also the Public Works portfolio, an appointment he held until his retirement in 1915

Carlyle was thus closely connected with the scientific activities of the Government of India for an unbroken period of eight years, during which he was particularly interested in agricultural research He was a great friend to the Pusa Research Institute, which he visited on many occasions, and he also found time to attend the meetings of the Board of Agriculture Under his fostering care the Institute developed with great rapidity the workers were constantly encouraged to give of their best The agricultural departments in the provinces were not forgotten Large sums of money were placed at their disposal for extensive seed farms for the production of pure seed of the new varieties of wheat created at Pusa and at other centres A new cane-breeding station was founded in South India at Coimbatore

Carlyle did much to foster and promote the co operative credit movement and to bring about effective liaison between its officers and those of the agricultural departments working in the Districts Other interests included the encouragement of the Indian Science Congress, the meetings of which his officers were permitted to attend while on duty, and at which they were given the greatest freedom in the reading and discussion of papers Carlyle was always insistent that the scientific workers under the Government of India should look upon themselves as free and independent investigators and not as members of a bureaucracy

The well being of agricultural research and the development of the co operative credit movement were only two of Carlyle's interests He did much to encourage the scientific study of forestry, he took a deep interest in the Survey of India and in the planning of New Delhi In these and other similar activities, the scientific workers concerned always found in him a sympathetic and responsive chief and one who spared no pains to understand their point of view and to make them feel that, so far as in him lay, they could rely on getting a square deal

---

DR J D GIMLETTE

DR JOHN DESMOND GIMLETTE, whose death on April 24 we regret to record, was born on February 28, 1867 After gaining medical qualifications (M R C S, L R C P, London), as from St Thomas' Hospital, he at first designed entering practice in the English colony at Lisbon Later he joined the medical service of the Federated Malay States (Selangor, Perak and Pahang), eventually becoming Residency surgeon for Kelantan and Kota Bahru

In Malaya, Dr Gimlette soon became interested in native medicaments and poisons, a subject which occupied him up to the end In Kelantan, a region little tainted by Western influences, his opportunities were enhanced by innate knowledge of the language and by the confidence which his frank and sympathetic nature impressed on the Malay Jealous in regard to native secrets, they allowed him to witness, for example, mysteries such as those of Main Peteri, which are recounted in his work "Malay Poisons and Charm Cures" (Third edition, 1929 London Churchill)

Though much had been done botanically by Ridley, Burkhill, the workers at Buitenzorg amongst others, by his medical knowledge Dr Gimlette was to forge a link between the plant as such and as a drug A happy collaboration with Mr I H Burkhill led to the publication of a translation of the "Malay Book of Medicine" by Inche Ismail (*Gardens Bulletin*, Singapore, 6, 1930), to this is appended a 'catalogue raisonnée' of very great value Thereafter, in conjunction with Messrs Skeat and Thomson, he started on a more comprehensive and ambitious work to be entitled 'The Malayan Medical Dictionary' This work, though more than half done, is interrupted by his death, however, it is hoped that his collaborators will be able to complete it without undue delay He was also the author of many minor contributions on medical subjects During the War he was in charge of a hospital ship (*Essequibo*)

From his retirement from active service, Dr Gimlette was condemned to a sedentary life through the unfortunate loss of a leg from intense erysipelatous infection, but he stuck to his self imposed tasks with courage and pertinacity With the cardinal virtues of sincerity and thoroughness, no more loyal or lovable friend could be found, and there are very many who mourn his loss, whilst admiring his constancy of purpose in good and in failing health, though withal cheerful and of good heart

A final note of sympathy must be struck for his devoted widow, two small daughters, his sisters and other relatives H E DURHAM

WE regret to announce the following deaths

Dr E W Nelson, chief of the U S Federal Bureau of Biological Survey, known for his work on the birds and mammals of North and Central America, on May 19, aged seventy nine years

Sir Walter P Buchanan Riddell Bt, principal of Hertford College Oxford, in 1922–29, chairman of the University Grants Committee, on June 5, aged fifty five years

Mr J J Fahie, author of several standard volumes on the life and work of Galileo, on June 12 aged eighty seven years

Maj Gen George O Squier, K C M G, member of the U S National Academy of Sciences, known for his work in connexion with electrical communications, on March 24 aged sixty nine years

News and Views

International Conference on Physics

A MEETING of the International Union of Pure and Applied Physics will be held in October next in London and a joint conference will be held with the Physical Society, under the presidencies of Prof R A Millikan and Lord Rayleigh The last meeting of the Union took place in 1931 at Brussels (see NATURE of September 19, 1931, p 485), when an invitation from the Royal Society to meet in London was withdrawn in order to enable the Union to accept the American invitation for a meeting at Chicago at the Century of Progress Exhibition in 1933 Prof R A Millikan was elected president, but on account of economic conditions the meeting was cancelled and the Royal Society renewed its invitation to meet in London The invitation was accepted and the meeting will be held on October 1–6 The work of the Union will include consideration of the report of the Commission on Symbols, Units and Nomenclature appointed at its last meeting The Commission, under the chairmanship of Sir Richard Glazebrook, has dealt with electrical, calorimetric and thermometric units and work has also been done in connexion with radiometric and acoustical units Dr Hales' committee on Instruments and Instrumental Methods will, it is anticipated, desire to consult the Union on a number of questions Apart from this formal business, it was felt that the occasion should also be utilised for international discussion on a subject or subjects now attracting general interest, certain aspects of the solid state of matter were suggested as suitable

THE Physical Society had already decided to hold a Conference on Nuclear Physics and it was agreed to combine the two proposals Thus the meeting will take the form of an International Conference, on the joint invitation of the International Union and the Physical Society, under the presidencies of Prof Millikan and Lord Rayleigh the details are being arranged by a committee representing the two bodies The discussion on nuclear physics will be opened by Lord Rutherford with a general survey of the subject Subsequent papers will deal with cosmic radiation, β ray transformation of radioactive elements, artificial transmutations by α rays, neutrons protons and diplons and new types of radioactivity, and the constitution of atomic nuclei Sir William Bragg will deliver an opening survey in the discussion on the theory of the solid state of matter Papers on interatomic forces will be divided into three groups dealing with electrovalent linkings, covalent linkings and van der Waals attractions, as special consideration will be given to the action of these forces in metals at the Aberdeen meeting of the British Association, this particular section of the subjects will not be so fully considered at this discussion Another group of papers will deal with the possible existence of a secondary structure in crystals, coarser than the fine structure detected by X rays, and its relation to physical properties The names of delegates of national unions adhering to the International Union of Physics should be sent to the secretaries of the Conference not later than August 1 Invitations are being sent to a number of physicists known to be interested in these subjects, others desiring to attend should send in their names not later than September 1 All communications should be addressed to the Secretaries, International Conference on Physics, Royal Society, Burlington House, London, W 1

Memorial to Sir Walter Morley Fletcher

THE public life of Great Britain suffered a loss of more than common magnitude through the death of Sir Walter Morley Fletcher, first secretary of the Medical Research Council, on June 7, 1933 He was then in his sixtieth year and in the height of those powers which he had used without stint in the advancement of knowledge for the relief of human suffering Walter Fletcher gave richly to the common weal, and it is fitting that some worthy tribute of an enduring kind should be paid to his memory An appeal has therefore been issued over the signatures of the Lord President of the Council, the president of the Royal Society and representatives of aspects of science and medicine with which Sir Walter Fletcher was particularly associated It is considered that the tribute should consist in the first place of a personal memorial, and secondly of the inception of some scheme for the furtherance of the cause which Sir Walter Fletcher had so much at heart It is therefore proposed first to commission a portrait bust, to be placed in a suitable setting in the entrance hall of the National Institute for Medical Research, at Hampstead The remainder of the sum collected will then be used as a fund for building—at the farm premises of the National Institute at Mill Hill—a Walter Fletcher Laboratory, to be devoted particularly to those nutritional studies in which he was so keenly interested This will not only provide an appropriate memorial, but also it will make an urgently needed contribution to the national equipment for work in what is at present among the most important of all branches of medical research All subscriptions should be sent to the Secretary, Fletcher Memorial Fund, 38 Old Queen Street, Westminster, S W 1

Telford Centenary Exhibition

THOMAS TELFORD, the distinguished civil engineer, died at his house at 24 Abingdon Street, Westminster, on September 2, 1834, at the age of seventy seven years, and a few days later was buried in the nave of Westminster Abbey For the last thirteen years of his life he was president of the Institution of Civil Engineers, and in connexion with the centenary of his death the Institution has arranged an exhibition which was open for inspection at the conversazione this week and will remain open each day at 10 A M – 5 P M until June 22 The materials for the exhibition have been gathered together mainly through the efforts of Sir Alexander Gibb, whose forbears were associated with Telford in some of his works Telford's whole life was devoted to engineering works of national importance, and his steady rise from a stone mason, working on Somerset House, to the head of his profession, was due to his wide knowledge, energy and sound judgment He constructed many hundreds of miles of roads, more than a thousand bridges, some of the most important canals in Great Britain and also did valuable work on harbours His most famous works included the Ellesmere Canal with the great Pont Cysylltau Aqueduct, the wrought iron suspension bridge over the Menai Straits and St. Katherine's Docks He took the liveliest interest in the formation and growth of the Institution of Civil Engineers, presenting to it a collection of books for the formation of a library and bequeathing to it several thousands of pounds. The exhibits collected for the occasion of his centenary relate to nearly all his activities and include plans, drawings, reports, note books, letters, portraits, etc A carefully annotated catalogue has been prepared which itself forms a valuable addition to the material relating to the great engineer

History of Derbyshire Industries

THE Newcomen Society held its summer meeting in Derbyshire on June 6–9, and the members were able to pay visits to many interesting works These included the Old Crown Derby China Works, the quarries of the Clay Cross Lime Co, the hosiery works of Messrs George Brettle and Co, Ltd and the Mill Close Lead Mine, Darley Dale At various places, some interesting machines and engines were inspected and at the works of the D P Battery Co two very fine water wheels were seen After the Society's dinner on June 7, two papers were read, one on the High Peak Railway, and the other on the history of some Derbyshire industries The latter was by Mr Rhys Jenkins, who gave in it brief reviews of the lead, iron and other industries from the earliest records Lead mining and smelting was carried on in Derbyshire by the Romans, and a number of pigs of lead with Latin inscriptions have been found It is stated that there are no fewer than 4,000 disused lead mines in the county, and that some seventy years ago the output was 4,000 tons per annum The lead smelting works near Lea appear to be the last in the county Definite evidence of iron working go back to the twelfth century, and Mr Jenkins traced the development from that time onwards One interesting feature was the records of distinct industries in various localities, chains being made in one place, sickles and scythes in another, and so on About a century and a half ago, there was a flourishing industry at Hartshorn, when hundreds of gross of wood screws were made weekly. Of Lombe's famous silk mill erected two centuries ago, nothing now remains, but its erection was an outstanding event in the history of machine building

High Speed Precision Photography

AN interesting demonstration was given on June 12 of a new development in the taking and timing of serial photographs of objects moving at high speed. The apparatus, which is easily portable, is the combined work of the Western Electric Co and Kodak Limited It was demonstrated that 2,500 exposures per second could be made of objects in normal day light or illuminated with ordinary '½ watt' type lamps on the standard small size Kodak film. The interest in the camera lies in its extreme simplicity. As the film has to move across the focal plane with speeds up to 50 feet per second, the usual intermittent motion must be dispensed with and a uniform motion substituted. Mounted between the lens (Kodak anastigmat *f*/1 8) and the film is a small slab of glass which rotates about an axis parallel to its own plane and passing through the middle of the slab This gives a lateral motion to the image in the same direction as that in which the film is moving Exposure is only allowed when the slab is approximately normal to the optic axis, when the lateral speed of the image will be $\omega T\ (\mu-1)/\mu$, where T is the thickness of the slab and ω its angular velocity There is no mechanical shutter other than the mounting of the slab, which intercepts the light twice for every complete revolution, and this combined motion of film and image takes the place of the more usual motion hitherto adopted The image of a moving dial is projected on to the corner of each exposure by an accessory internal optical system The motion of the dial is controlled independently by a 200 fork controlling a synchronous motor The time spacing on the image can be read to $\frac{1}{1000}$ sec The demonstrations of muscular reaction times and of splashes were extremely good, but it was noticed that in the comparatively simple image of a falling steel ball, there was a slight elongation

International Broadcasting Union

THE International Broadcasting Union (or the Union Internationale de Radiodiffusion—to use its official title) is making its first official visit to Great Britain at the meeting which is being held in London from June 12 until June 20 The issue of *World Radio* of June 8 contains a series of articles describing the organisation and work of the Union When the Union was founded in London in March 1925, eight European countries were represented, and according to the minutes of that meeting it was estimated that the broadcasting stations in Europe at that moment radiated a total energy of 80 kilowatts, of which 43 kilowatts emanated from stations in Great Britain At the present time, in the tenth year of the Union's existence, twenty five countries have members within the Union and the radiated energy of more than 250 stations included within what is officially recognised as the European zone is about 4,250 kilowatts The particular function of the Union with which the listening public is probably most familiar is that of policing the ether'—in other words maintaining the wave lengths of stations so far as possible uninterrupted by those of other stations

THIS, however is only one of many useful and essential duties performed by the Union with the aid of commissions dealing with legal, programme relay and technical matters In the course of its work a spirit of co-operation has been established among the European broadcasting authorities as a result of their common membership of the Union, and in addition strong and valuable links have been forged with the broadcasting organisations of other continents, notably the great American chains and the corporation which controls Japanese broadcasting Moreover, the Union has striven throughout its existence to promote that good understanding between nations, which is one of broadcasting's most valuable contributions to national life Since the inception of the Union, the president of the Council has been Sir Charles Carpendale, one of the controllers of the B B C while Mr A R Burrows, a pioneer of British broadcasting, has filled the post of secretary general in a popular and efficient manner at the Geneva office of the Union

British Antarctic Expedition

SOME further details of Mr J R Rymill's forthcoming antarctic expedition are published in the *Geographical Journal* of June It is hoped to leave Great Britain early in September in the *Penola*, a three masted topsail schooner of about 200 tons with a length of 112 ft The *Penola* which is fitted with a 100 H P Diesel engine, was built in 1908, she is of oak, and is now being reconditioned and sheathed with greenheart at Southampton A De Haviland Puss Moth aeroplane, capable of carrying three men, or two men with a survey camera, is being taken Sixty dogs from West Greenland and twelve sledges will be carried Messrs Hampton and Stephenson, with the dogs and much of the equipment, will leave for the Falkland Islands in July, and Mr Rymill with the rest of the expedition sailing in the *Penola* will meet them there in October *Discovery II* is to assist in the transport of stores as far as Deception Island Beyond that, the plans of the expedition will depend on the state of the ice, but it is hoped to set up the base house on Hearst Land in order to explore east and west by sledge It may however be necessary for the ship to return to Deception Island if no good harbour is found in the far south The expedition proposes to return to England in May 1937

Jubilee of the Society of Dyers and Colourists

COMMEMORATING the foundation fifty years ago, of the Society of Dyers and Colourists a jubilee issue of the Society's *Journal* has recently been published Of the twenty two articles which it contains, some are reviews of the advances which have been achieved during that time and others deal chiefly with the present state of knowledge in various departments of the science and art of dyeing A foreword is contributed by Prof G T Morgan who as an active worker in dye chemistry and as president of the oldest chemical society in the world refers to the rise of the British colour industry and to the means whereby Parliament has safeguarded its growth Mr J Huebner contributes an interesting account of the early history of dyeing and Mr A H Brewin sketches the history of the Worshipful Company of Dyers, London Prof A G Green discusses landmarks in the evolution of the dyestuff industry during the past half century and Dr H Levinstein contributes some pertinent observations on British patent laws Articles on the constitution of cellulose by Prof W N Haworth on substitution in the benzene nucleus by Prof R Robinson, and on the relation between the constitution and substantivity of dyes by Prof P Ruggli serve as a reminder, should any be necessary, of the close dependence of a successful chemical industry on researches in 'pure' chemistry Among the other articles, no less interesting because of a technical character, are accounts of progress in various dyeing, cleaning, bleaching and finishing operations applied to textiles, furs and leather, and a review of the chemistry and technology of rubber and synthetic resins The price of the special issue is 25s , but members of the Society may purchase one copy at a privilege price

The National Physical Laboratory

THE report of the National Physical Laboratory for the year 1933 is a quarto pamphlet of 264 pages and 50 figures, many of them plates, and provided with an index of 10 pages The condition of industry has reduced the demand for routine tests of instruments and for investigation of problems of manufacture, but the research programmes of the Executive Committee and of the Boards and Committees of the Department of Scientific and Industrial Research have been pressed forward An important and promising method of bringing provincial industries into touch with the Laboratory has been tried during the year, by the senior members of the staff lecturing on the general work of the Laboratory and on specific problems of local industries at many large towns in the country Each department of the Laboratory provides its report, and each report contains matter of great interest which is well illustrated by figures and easily followed The Radiology Division has for example, investigated the effect of heat treatment on metals which have been cold worked previously, and finds that a magnet steel retains its magnetic properties better when in a state of strain than when the strain is relieved by heat treatment, and that transformer steel is the better for being free from internal strain On one hand, the Department has tested for internal flaws two Diesel engine connecting rods of 4 in diameter, and on the other, for the Medical Research Council the structure of human teeth

Quieter Motor-Cars

A RECENT report by Science Service gives a résumé of the discussions during the annual general meeting of the Society of Automotive Engineers at Detroit It was stated that in the earlier days of motoring the thrill of passing another motorist was incomplete unless your motor had a louder and deeper roar than his Now motorists are worried even by the amount of noise their tyres make Modern car mechanisms are so improved that at speeds below 40 miles an hour this noise is clearly audible In fact some motorists utilise it to keep the speed constant The low buzz or flutter is due to the trapping of air in parts of the tyres Noise in motor cars can be eliminated in two ways, either by absorption or cancellation by interference In mufflers which absorb sound, the sound energy is converted into heat by resonators owing to the friction of waves passing through small holes and the use of porous materials Mufflers that depend on wave interference get one part of the sound in opposition in phase with the other, so that they partially cancel One new type of muffler passes part of the exhaust gas through a venturi tube and it then operates the wind shield cleaner A silencer which utilises both resonance chambers and absorbing materials is sometimes effective in preventing intake noise (power roar) The noise to passengers can be considerably reduced by padding the bodies of the saloon by sound absorbing material in the same way as the acoustical properties of radio studios can be improved One result of making motor cars quieter is that the driver often unconsciously increases the speed

Venereal Disease in Literature

IN a paper on this subject read on May 30 before the Medical Society for the Study of Venereal Diseases Dr J D Rolleston said that in no department of medicine is a knowledge of the lay writers on the history of the subject more necessary than in the domain of venereal disease The information furnished by poets, dramatists novelists and historians forms a valuable supplement to that derived from the study of contemporary medical works In a survey of non medical literature from the earliest times down to the present day containing any references to the three principal venereal diseases, Dr Rolleston came to the following conclusions There is no definite evidence that syphilis existed in Biblical times, classical antiquity or the Middle Ages In striking contrast with the absence of any certain reference to the existence of syphilis in Europe before 1495 an immense amount of literature, lay as well as medical, dealing with the new disease followed that date On the other hand, gonorrhœa, of which the first description is in Leviticus, dates from remote antiquity, but for about 250 years was identified with syphilis, the popular monosyllables for the two diseases being applied indiscriminately in lay literature to syphilis or gonorrhœa Chancroid was probably as old as gonorrhœa and was well known in classical antiquity and the Middle Ages

Human Sterilisation

THE April number of the *Eugenics Review* is largely devoted to the subject of sterilisation Major Leonard Darwin makes a detailed analysis of the report of the Departmental Committee known as the Brock Report, Dr E Mapother discusses the necessary safeguards in eugenic sterilisation and Prof Hans Maier of Zurich contributes an article on practical experience of sterilisation in Switzerland where it has been practised in certain cantons under medical supervision for more than fifty years The legal aspects of sterilisation in Great Britain are discussed by Mr Cecil Binney, and Dr C C Hurst contributes a paper on the genetics of intellect An account is also given of discussions in the House of Commons, and the speech of Mr Hugh Molson, M P , in moving that H M Government give immediate consideration to the recommendations made unanimously by the Committee is reproduced in full In all cases, emphasis is laid upon the need that sterilisation should be voluntary, and with proper safeguards, as any element of compulsion defeats its own ends

Cancer Research

In March 1933 the International Cancer Research Foundation, established by Mr William H Donner of Philadelphia, awarded a sum of £1,000 per annum for a period of two years to the Research Institute of the Cancer Hospital (Free), London, in support of investigations into factors which underlie the origin of malignant growths This grant has provided two research scholarships which are held by G A D Haslewood, who is working with Dr J W Cook in the Research Institute, and by Miss Edna Roe, who is studying the molecular structure of carcinogenic compounds by physical methods, under Dr Mayneord in the Physics Section of the Radiological Department of the Cancer Hospital The grant has also defrayed a part of the cost of this work Under the direction of Dr Cook, Haslewood has recently prepared a very active cancer producing compound, methylcholanthrene, from another compound, deoxycholic acid, which is known to occur in the human body To assist in further developments of this work, the Trustees of the International Cancer Research Foundation have now decided that this grant shall be continued for an additional three years, until June 1, 1938

Ross Institute Industrial Advisory Committee

Details of the activities of this Committee in promoting health in the tropics are given in the report of a meeting held on March 27, with Mr G H Masefield in the chair As a result of health measures introduced in the copper mines of Northern Rhodesia, at Zambezi Bridge, and in the tea gardens in Assam, sickness due to malaria has been much reduced. Dr McCombie described an experiment in a tea garden with the drugs atebrin and plasmoquin as preventives of malaria, with a saving of 1,941 sick days among the coolies, but the treatment is too costly to be a business proposition (11 annas per head) On the same estate anti mosquito larval measures proved much cheaper (2 6 annas per head) and resulted in a saving of 7,068 sick-days Reference was made to the 'eye fly pest' in India and Ceylon, caused by numbers of a small fly (*Microneurum funicola*) which settle upon the eye, and by the bacteria which they carry induce ophthalmia The breeding habits of this fly have still to be discovered, but by providing infected cases with wire gauze spectacles, these epidemics may be controlled in large measure by preventing carriage of infection

Official Chemical Appointments

The Institute of Chemistry has recently issued the eighth edition of the 'List of Official Chemical Appointments" (Institute of Chemistry, 30 Russell Square, London, W C 1 1934 Price 5s) Since the seventh edition was published three years ago, much revision has been necessary, but the list is now a useful, up-to-date compendium of official appointments It consists of a list of official appointments in Great Britain, Northern Ireland and the Irish Free State, a list of appointments in the British Dominions, Colonies, Protectorates, Egypt and the Sudan Provinces, information concerning societies and institutions devoted to chemical interests, and statutes, orders, etc, which affect official chemical appointments Names of university professors, lecturers and demonstrators, and public and secondary school masters are also included There are indexes of names and places respectively A full contents, classified, and with each group arranged alphabetically, renders a general index unnecessary This is a useful list, well arranged, so that reference is an easy matter

Pollen Carried by Dust Storm

Mr O C Durham, chief botanist of the Abbott Laboratories in North Chicago, exposed collecting slides through the period of the remarkable dust storm recently experienced in the United States His collections, as a result of the examination of these slides, indicate a fall of some 34 7 tons of dust per square mile of which no less than 3 4 tons would be represented by oak pollen This percentage of pollen certainly seems a striking phenomenon and has its interest in connexion with the use made of pollen distribution in strata of vegetable remains, as an indication of the vegetation in these areas at the period when the remains were deposited Mr Durham's observations are reported by Science Service, Washington D C under date May 14

Micrometer Scales on Photomicrographs

In the May issue of *Watson's Microscope Record*, J A Lord pleads for the inclusion of a scale of measurement on each published photomicrograph, so that a visual estimate of the size of the objects represented is readily possible He also points out the desirability of including such a scale of measurement on lantern slides made from photomicrographs so that, irrespective of initial or final magnifications, the dimensions of the objects can be estimated as seen on the screen Appended to his article is a convenient form of scale by the aid of which a micrometric scale, correct for each given magnification, can quickly be marked upon a photograph or a lantern slide

Greenland Whale at the Natural History Museum

The skeleton of a Greenland whale, which has been presented by the president and council of the Royal College of Surgeons to the trustees of the British Museum, has been removed from the College and will shortly be erected in the new Whale Hall at the Natural History Museum The specimen was originally purchased by the College in 1864 from Prof Reinhardt, of Copenhagen Although the Greenland whale is commonly used as a textbook example of the Cetacea, complete skeletons of this species are very rare in museums, and in Great Britain there appears to be a record of only one other, a young one, which is in the Anatomical Museum of the University of Edinburgh

The Men of the Trees

The ninth annual report of this voluntary society, which attempts to bring together those interested in trees, their planting, cultivation and protection, shows that it is still active and growing in membership ("The Men of the Trees" Ninth Year's Report and Review of the Tree Year 1933 Pp 36+4 plates London Hon Secretary, 32 Warwick Road, S W 5 6d) Whilst the death duties cause the break up of many old well wooded estates and realisation upon their timber, the Forestry Commission still suffers under a cut of £400,000, so that its planting programme is inevitably cut down Under these conditions, there is ample room for the activities of this society, which in its ninth annual report gives an extensive account of an important statement upon the position of forestry in the Empire made at the annual meeting of the society by Prof Troup, of the Imperial Forestry Institute, Oxford

Works on Astrology and Alchemy

AN interesting catalogue of second hand books on astronomy, astrology, alchemy and the occult sciences has recently been published by Émile Offenbacher, 10 Rue Pasquier, Paris, 8^e Among the more attractive items may be noted the first Italian edition of Euclid with a commentary by Tartaglia (1543), a first edition of Galileo's Istoria e dimostrazione intorno alle macchie solari" (1613), a second edition of Reisch's Margarita philosophica" (1504), a copy of Thomas Radini s Sideralis abyssus ' (1511), and the first edition of Kertzenmacher s Alchimia" (1538) A score of books on the Rosy Cross are included and all the items appear to be very moderately priced Bibliographical notes are given in sufficient detail a feature which, with the numerous illustrations, will make the catalogue a useful book of reference even when the books it describes have found scattered homes in the libraries of collectors We hope that M Offenbacher will give us further catalogues of the same kind, for they represent a real contribution to the history of science

Announcements

THE Albert Medal of the Royal Society of Arts for 1934 has been awarded to Sir Frederick Gowland Hopkins, president of the Royal Society, for his researches in biochemistry and the constituents of foods The medal is awarded annually for distinguished merit in promoting arts, manufactures, or commerce

PROF A C SEWARD, professor of botany in the University of Cambridge, has been elected a foreign member of the Botany Class of the Royal Swedish Academy of Sciences

SIR FREDERICK GOWLAND HOPKINS will unveil a plaque to William Hyde Wollaston at 14 Buckingham Street, W 1 on Wednesday, July 4, at 3 30 p m

PROF P L MERCANTON, professor of meteorology and geophysics in the University of Lausanne, has been appointed director of the Central Meteorological Station of the Commission fédérale suisse de Météorologie, in succession to Dr J Maurer, who has recently retired

THE following appointments in the Colonial agricultural service have been made by the Secretary of State for the Colonies Mr A K Briant, to be agricultural superintendent, St Vincent , Mr. M Halcrow, to be agricultural officer, Kenya , Mr N M Wight, to be district agricultural officer Tanganyika , Mr H W Jack (economic botanist Federated Malay States), to be director of agriculture, Fiji , Mr F L Squibbs (assistant agricultural officer Dominica), to be director of agriculture, Seychelles

IT is announced in the *Times* of June 9 that the Belgian National Scientific Research Fund has made a grant of 750,000 francs (more than £7,100) for the erection in Brussels of the Albert Library in memory of the late King of the Belgians The Société Financière Mutuelle Solvay has subscribed 500,000 francs

ADVISORY leaflets on matters of interest to farmers recently issued by the Ministry of Agriculture and Fisheries, include one on the use of seaweed as manure, pointing out its special value for crops which require a large amount of potash and are benefited by salt Other leaflets deal with birds of agricultural significance (more or less) , they include the kestrel, landrail and nightjar Another describes the activities, life history and control of the turnip gall weevil

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A principal of the Municipal Technical College Halifax—The Education Officer Education Offices West House Halifax (June 18) An assistant master to teach surveying and general science at the Pontardawe Mining and Technical Institute—The Director of Education County Hall Cardiff (June 18) A teacher of botany and chemistry at the Ashford and Folkestone Technical Institutes—The Principal, Technical Institute, Ashford (June 22) A lecturer in chemistry at Chesterfield Technical College—The Clerk to the Governors, Technical College, Infirmary Road, Chesterfield (June 23) A City electrical engineer for Plymouth—The Town Clerk, Municipal Buildings Plymouth (June 25) A mining instructor at the County Secondary School and Cumberland Technical College, Workington—The Principal (June 23) A teacher of general chemistry at the Northern Polytechnic, Holloway, London, N 7—The Clerk (June 27) A veterinary officer to the County Borough of Wallasey—The Town Clerk, Town Hall, Wallasey (June 28) A junior lecturer in electrical engineering at the Military College of Science, Red Barracks, Woolwich, S E 18—The Commandant (June 30) A district agricultural organiser for the East Anglian Institute of Agriculture, Chelmsford—The Clerk of the Council, County Hall, Chelmsford (July 2) An assistant lecturer in anatomy and an assistant lecturer in physiology at the University College of South Wales and Monmouthshire, Cardiff—The Registrar (July 7) A teacher of domestic science at the Princess Mary's Village Homes (Home Office Approved' School), Addlestone, Surrey—The Secretary An assistant lecturer in mathematics at University College, Hull—The Registrar A second assistant port engineer to the Basrah Port Directorate, Iraq—The Crown Agents for the Colonies, 4, Millbank, London, S W 1

Letters to the Editor

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications*]

The Factor $\frac{137}{136}$ in Quantum Theory

IT has been suggested by W N Bond[1] that in some or all of the attempts to determine e/m experimentally, *the quantity actually found is* $\frac{136}{137}$ e/m, for if the experimental results are corrected in accordance with this hypothesis they are found to be in satisfactory accordance with my theoretical values of the fine structure constant (137) and mass ratio (1847 6) R T Birge[2] has confirmed this and, quoting three important recent determinations of e/m, he has shown that the agreement is extremely close

On theoretical grounds it seems likely that Bond s hypothesis is right In my earliest paper on the subject[3], I gave the value of the fine structure constant as 136, since I found the Coulomb energy of two elementary particles to be $1/136r$ in natural quantum units This energy was $\frac{137}{136}$ times too large, because I had not allowed for the 137th degree of freedom arising from the indistinguishability of the particles *Bond s hypothesis implies that I am not the only victim of this mistake*, current quantum theory in deriving from observational data the proper energy or *mass m* of an electron has also obtained an energy $\frac{137}{136}$ times too large If so the cause is presumably the same namely neglect to take into account the degree of freedom due to indistinguishability

There is nothing mystical in the effect of indistinguishability It occasions, not an objective difference of behaviour, but a difference in what we can ascertain about the behaviour and hence a difference of treatment In the dynamics of two particles we have to describe the change with time of the positions, momenta and spin components (or of a probability distribution of them) of the particles which we call No 1 and No 2, and also we have to describe a growing uncertainty whether the particle, called No 1 at the time t is the original No 1 If the probability that it is the original No 1 is $\cos^2\theta$ (so that the probability that it is the original No 2 is $\sin^2\theta$) the permutation variable θ will be a function of the time and have all the properties of a dynamical variable, giving therefore an extra degree of freedom of the system and having a momentum (energy of interchange) associated with it When, however, the particles are distinguished without uncertainty, θ is constrained to be zero, and this degree of freedom is lost

Thus for the treatment of two indistinguishable particles, we have to start with an *a priori* probability distributed over a closed domain of 137 dimensions, whereas for two distinguishable particles it is distributed over a closed domain of 136 dimensions Naturally, the average values of characteristics of the distribution are slightly different in the two treatments In particular, the energy tensor of the *a priori* probability distribution, which is identical with the metrical tensor $g_{\mu\nu}$ of macroscopic theory is different Hence *the two kinds of treatment are associated with different metrics of space time* It seems clear that a factor $\frac{137}{136}$ (neglected in current quantum theory) will be introduced by the change of metric when we equate the space occupied by the indistinguishable particles of quantum theory to the space occupied by the distinguishable parts of our measuring apparatus

It may be asked Why does this factor affect the mass of the electron but not that of the proton ? The discrimination is, I think not strictly between the proton and electron but between the resultant mass ($M + m$) which is nearly the mass of a proton, and the reduced mass of the relative motion $Mm/(M + m)$ which is nearly the mass of an electron, for it is in the relative motion that the question of distinguishing the two ends of the relation arises It may also be asked why the factor $\frac{137}{136}$ which refers especially to a system of two particles, applies irrespective of the number of particles The answer is that the metrical ideas of quantum theory are borrowed from those of relativity theory, and since the latter are based on the interval between two points the former refer correspondingly to the wave function of two particles

Production of Very Low Temperatures by the Magnetic Method Supraconductivity of Cadmium

A YEAR ago the first experiments for producing very low temperatures by adiabatic demagnetisation of certain paramagnetic substances, as suggested by Debye[1] and Giauque[2] were carried out, by Giauque and MacDougall[3], and also by de Haas Wiersma and Kramers[4] Continuing our former experiments[5] on the magnetic method we have constructed an apparatus for investigations in the region of lowest temperatures As we shall soon give a detailed report of some calculations and experimental work, we will mention here only some of our results

We succeeded in so choosing the conditions that, on one hand, the removal of the heat of magnetisation was completed in a few minutes, on the other hand the condensation of the residual gas on the cooled substance took place very rapidly, the latter being necessary for keeping the low temperatures attained Hence one had to keep the magnet switched on only for a few minutes

Using 0 5 gm of manganese ammonium sulphate, a substance we found to be most suitable, we reached 0 1°, starting at 1° and 6,000 gauss (a stronger magnet was not at our disposal) The temperature was determined by measuring the susceptibilities and extrapolating as in the experiments mentioned above, this procedure being subject to the same objections as discussed there The thermal insulation in our arrangement was such that it took, for example, one hour and a half to warm up from 0 18° to 0 26°

We then made experiments in cooling down other substances with the paramagnetic salt, looking first *for supraconductivity in the case of cadmium* For this purpose a tablet was pressed out of equal volumes of cadmium and manganese ammonium sulphate

The experiments showed that cadmium becomes supraconductive This was recognised by the appearance of persistent currents, a method of observation similar to that used by Tuyn and Kamerlingh Onnes[6] in investigating powdered substances The same mutual inductance, which served for the measurement of the susceptibility of the salt, was used to detect these persistent currents Extrapolation to zero measuring field gives a transition point of about 0 6°

Phase Variations of Reflected Radio-Waves, and a Possible Connexion with the Earth's Magnetic Field in the Ionosphere

THE apparatus used for measuring the phase variations of the reflected radio waves, already described[1] consists of a transmitter modulated by the alternating 42 cycle current to emit periodic signals of, say 1/1000 sec duration The receiver consists of a one stage screen grid high frequency amplifier a plate circuit detector and a final one stage continuous current amplifier The observations are made by a cathode ray oscillograph the spot of which is deflected along the time axis by the same alternating current The detector valve is made to oscillate at a frequency little different from that of the transmitter, then beat curves are observed on the oscillograms corresponding to the reflected wave trains

The position of the beat curve is a measure of the virtual height of reflection Moreover when the echoes do not present phase variations (optical path constant), the beat curves are absolutely fixed, this is due to the fact that the oscillating detector is synchronous with the transmitter at the beginning of the emission of the signal When the phase of the reflected waves changes (by variation of the optical path), the beat curves present an apparent movement, from which, as in an interferometer it is possible to determine the velocity and the sense of the optical path variation (For an optical path change of even a fraction of a wave length the modification of the beat curve is easily visible) When the ionic density increases, the optical path diminishes, and inversely

The most interesting phenomenon that I have observed is that the two echoes produced by the magneto ionic double refraction sometimes present phase variations of opposite sense This can be explained, in the present state of our knowledge, only by admitting a variation of separation of the two echoes, possibly following a change of intensity of the earth's magnetic field in the ionosphere Whatever effects the change of ionic density, it causes optical path variations in the same sense for the two echoes In correspondence with the periods during which I have observed phenomena of this type, even the magnetic field at the earth's surface shows remarkable variations

Researches are in progress to investigate further the relationship between such variations in the ionosphere and magnetic conditions at the earth's surface

Radio Exploration of the Ionosphere

PROF APPLETON'S recent letter[1], reporting the measurement of the magnetic intensity *H* in the upper ionised region of the atmosphere, illustrates anew the power and value of radio methods of upper air investigation It affords clear evidence, which probably few workers on the earth's magnetism expected ever to gain of the decrease of the field with height This decrease is predicted by the Gaussian potential theory but not without some small uncertainty due to the slight non uniformity of the earth's magnetisation, and also to the existence of electric currents in (and perhaps beyond) the atmosphere

Should it become possible to determine *H* by radio methods to within 1 per cent, the results may afford a check on the magnetic theory provided that we know also the height to which the measures refer At present there is difficulty in interpreting the equivalent heights' attained by radio waves and therefore the immediate value of Prof Appleton's measures of *H* may lie chiefly in the independent estimate of height which they afford by inference from magnetic theory In the latitude of Great Britain and except in periods of notable magnetic disturbance the theory seems quite adequate for this purpose Nearer to the auroral zone, however, where the upper air electric currents are both more powerful and more localised the radio measurements of *H* may become of great value in mapping the magnetic field

Absorption Spectra of Aldehydes

1 RECENT observations of the ultra violet absorption bands in the vapours of a series of homologous aldehydes have disclosed a vibrational structure, which is very similar throughout the series, since 35 measurements have given an average separation of 1025 cm^{-1} in the spectra of the higher homologues, although this interval increases to 1053 cm^{-1} in acetaldehyde The corresponding frequency 1187 cm^{-1} in formaldehyde has been attributed to a nuclear vibration of the excited molecule  $\genfrac{}{}{0pt}{}{H\nwarrow}{H\swarrow}\!\!>\!C\rightarrow\;\leftarrow O$, and there can be little doubt that we are now dealing with a similar nuclear vibration  $\genfrac{}{}{0pt}{}{R\nwarrow}{H\swarrow}\!\!>\!C\rightarrow\leftarrow O$ of the other aldehydes

2 The maximum absorption is approximately constant at about 2900 A or 34,500 cm^{-1} In

the case of formaldehyde this electronic excitation has been shown unambiguously by Dieke and Kistiakowsky[1] to be associated with a change of electric moment in the y plane that is perpendicular to the C=O axis and in the plane of the two hydrogen atoms The excitation of the other aldehydes may be presumed to proceed in the same way Mulliken[2] has pointed out that such an electronic transition will appreciably affect the C–H bonds a conclusion which Norrish[3] had reached previously on chemical grounds

3 These considerations may be extended to the ketones $^{R^1}_{R^2}{>}C=O$ where our own preliminary observations on acetone showed ill-defined separations of about 1100 cm^{-1} The separations described by Bowen and Thompson[4] are twice as large and irregular in magnitude moreover the frequency 2900 cm^{-1} of the Raman line with which they compare these separations is characteristic of valency vibrations involving hydrogen atoms rather than those postulated under (1) above It is therefore clear that further confirmation is required before these larger separations can be accepted as characteristic of the >C=O group

4 Striking results have been obtained with acrolein which (through the kindness of Prof W L Bragg) we have examined with the 21 foot grating at Manchester In all other aldehydes except formaldehyde the fine structure is either too complex to be analysed at present or too diffuse to be recorded in detail The absorption spectrum of acrolein however shows several bands which have a fine structure rivalling those of the diatomic gases in simplicity and sharpness These bands consist of sharp regularly spaced lines of which as many as 20 may be seen in a range of less than 20 A They resemble the rotational lines of the R branch of a diatomic molecule but they present a remarkable anomaly which does not appear to have been observed previously since the moment of inertia of the ground state calculated on the assumption that the lines constitute single rotational series is different for the various bands instead of being constant throughout

Relation of Materials of the Cell Nucleus to the Lethal Action of Ultra-Violet Radiation

SEVERAL workers have suggested the possible relationship of materials of the cell nucleus to the lethal action of ultra violet radiation[1–4] but there seems to have been no systematic study of the problem heretofore

The lethal action of such radiation for cell life has been found to begin abruptly at about 2950 A and to continue for shorter wave lengths[5–11] By exposing such materials as thymus nucleic acid adenine uracil etc to ultra violet radiation through various long wave pass filters and studying their absorption before and after irradiation we have found 2950 A to be approximately the longest wave length effective in their destruction

Absorption studies of uracil[12] etc, in concentrations approximately that in which these substances appear in the cell nucleus show them to have marked absorption in the ultra violet shorter than 2900 A The long wave leg of the absorption band rises steeply between 3000 A and 2900 A its position agreeing closely with the wave length threshold for the lethal action of ultra violet radiation on bacteria

Finally thymus nucleic acid yeast nucleic acid etc have been found to have marked absorption maxima at about 2600 A[12 13] This agrees quite closely with the optimum wave length region for the lethal action of ultra violet as found by various workers[8 9 11 14–17]

These three types of results indicate that materials of the cell nucleus play an important part in the lethal action of ultra violet for at least many kinds of micro-organisms

When the rays shorter than about 2900 A are filtered out the irradiation of nuclear compounds has been found to bring about absorption changes indicative of the formation of isomers or more complex compounds The possibility that these products of long wave irradiation may be growth promoting or cell division promoting is being investigated

Full details of these experiments will be published elsewhere

Hæmorrhages in Chicks Reared on Artificial Diets a New Deficiency Disease

DURING work on the sterol metabolism of chicks[1 2] it was observed that the animals often exhibited extensive internal hæmorrhages when they were fed a ration consisting of vitamin A free casein 20 Marmite 10 salt mixture 4 5 starch 65 5 and varying amounts of cod liver oil concentrates The hæmorrhages were subcutaneous or intramuscular on the breast legs and wings and were accompanied by certain pathological changes in the horny stratum of the gizzard

The disease closely resembles scurvy but it has been shown that vitamin C either in the form of lemon juice (up to 77 c c in 59 days) or pure ascorbic acid (given by mouth or subcutaneously) in very large doses was without the slightest influence on the occurrence of the symptoms It has nothing to do with lack of vitamin A D B_1 B_2 fat or cholesterol

When chicks are fed a ration consisting entirely of cereals or seeds plus salts, the hæmorrhages fail to occur The cause of the disease must therefore be a *deficiency in an antihæmorrhagic factor different from vitamin C and occurring in cereals and seeds*

The histological features of the symptoms as well as the concentration and further characterisation of the antihæmorrhagic factor are being investigated further

Optical Rotatory Power

AN interesting mathematical derivation of the rotatory power of a simple organic compound has just been published by S F Boys[1] from which conclusions are drawn regarding *inter alia* the influence of solvents upon the magnitude of the rotation The author s comments on the effects of association and his classification of active solutes into three main groups namely non polar polar and those capable of entering into co ordination or complex union with the solvent are in agreement with the views arrived at by one of us from experimental data[2]

We are at present engaged in investigating the behaviour of optically active saturated hydrocarbons towards change of solvent using *d* pinane methyl menthane and other compounds as the non polar solutes We find that the rotation in such cases is chiefly governed by the refractive index of the solvent medium This point is illustrated by the following values for *d* pinane in dilute solution

d Pinane in Solution ($c = 3\ 5$)

Solvent	n_D	$[\alpha]_D$	Solvent	n_D	$[\alpha]_D$
Acetonitrile	1 3460	+18 7°	Methylene dichloride	1 4237	+21·0
Methyl alcohol	1 3312	19 3	Heptane	1 3867	21 1
Acetic acid	1 3715	19 5	Chloroform	1 4464	21 8
Nitromethane	1 3813	19 8	Carbon tetrachloride	1 4607	22 9
Acetaldehyde	1 3316	20 1	Methyl iodide	1 5293	23 6
Hexane	1 3760	20 1	Methylene iodide	1 7559	26 6
Acetone	1 3589	20 9	Carbon disulphide	1 6204	28 1

A large number of aromatic solvents have also been examined which fall into their appropriate positions in the above table The refractive indices quoted are those of the pure solvent but the results strongly support the prediction of S F Boys that the rotation of non polar solutes will be dependent on the refractivity of the solution An interesting point is that the specific rotation of pinane in the homogeneous state (n_D 1 4624 $[\alpha]_D + 22\ 95°$) is practically unaltered when the compound is dissolved in carbon tetrachloride (see table) In this case solvent and solute have almost identical refractive indices

Similar results are being obtained with other hydrocarbons full details of which will be published later

Raman Spectra of Benzene and Hydrogen Iodide in the Liquid and Solid State

A SYSTEMATIC investigation at low temperatures of the oscillation and rotation Raman spectra of simple molecules as they are affected by their state of aggregation and by temperature seems to us of great importance, for the transition from the gaseous to the liquid state will show mainly the influence of density, while in the transition from the liquid to the solid state the orientation of the exchange forces due to the crystal structure may have some influence on the Raman lines Moreover having ascertained the dependence of the Raman spectra upon temperature we are in the position to say something about the magnitude of the exchange forces and the rotation of the molecules in the crystal

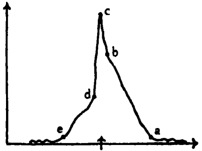

FIG 1

The whole investigation makes the utmost demands upon the low temperature apparatus as well as upon the spectroscopic arrangement We have constructed a low temperature apparatus which enables us to prepare a clear and transparent crystal and to keep it at a constant temperature (±0 1° C) between +30° and −150° C for any length of time (up to 100 hours) the type of spectrograph used is the big Steinheil with three glass prisms In order to get the best possible results from it we have increased the rigidity of its mechanical parts and have regulated the temperature of the room As source of light we employed the line λ 3888 A from a helium discharge tube to avoid any disturbance by a continuous back ground (for the details of the apparatus see the paper shortly to appear in *Z phys Chem* (B)) The following are data for the spectrograph dispersion at λ 4200 A small camera ($f = 270$ mm) 21 A/mm, large camera ($f = 650$ mm) 8 7 A/mm, diameter of the camera lens 65 mm

We have obtained the following results

Benzene

ν_R (cm) for liquid	992 2	983 3	1176 7	1605 3
ν_R (cm) for solid	990 5	982 3	1174 7	1602·9
Decrease (in wave numbers)	1·7	1 0	2 0	2 4
Decrease (per thousand)	1 7	1 0	1 7	1 5

There is thus a small decrease in the wave numbers if we go from the liquid to the solid state This change which is much larger than the uncertainty of ν_R (not more than 0 1–0 3 per thousand) means a small weakening of the binding forces of benzene in the solid state The half width of the line 992 2 cm^{-1} will be less than 4 cm^{-1} in accordance to Grassmann[1]

Hydrogen Iodide

Gaseous state[2]	2233 cm.$^{-1}$
Liquid	2164 9 ± 1·0 cm^{-1}
Decrease	68 1 cm^{-1}
Decrease per thousand	31
Solid state	2159 9 ± 1·0 cm.$^{-1}$
Decrease	5·0 cm.$^{-1}$
Decrease per thousand	2 3

For liquid hydrogen iodide we find a Raman line of a very diffuse character As in the case[2] of hydrogen chloride and bromide it has a complex structure The wave numbers in the liquid and solid state as compared with the gaseous state are given in the accompanying table The structure of the line in the liquid may be seen from Fig 1 The points marked on the curve have the following wave numbers *a* 2178 cm^{-1} *b* 2167 cm^{-1}; *c* 2165 cm^{-1} *d* 2162 5 cm^{-1} *e* 2151 cm^{-1} It may be emphasised that the structure and the wave numbers are not very accurately known

From these results it will be seen that although the low temperature apparatus already used is quite adequate for our purpose a spectrograph of higher dispersion will be necessary if we are to carry this investigation further We have therefore begun to construct a new type of spectrograph with a liquid prism

Magnetic Moment of the Deuton

IN a previous note[1] we reported together with Mr Frisch on experiments concerning the deflection of a beam of ordinary hydrogen molecules in an inhomogeneous magnetic field From these experiments we were able to derive the magnetic moment of the proton The value obtained was 2 5 nuclear magnetons (not 1 as expected theoretically)

We have now performed similar experiments with a beam of heavy hydrogen molecules and derived in a similar way the magnetic moment of the deuton The value obtained is about 0 7 nuclear magnetons[2]

A detailed account of these experiments will appear in the *Physical Review*

Electron Microscopy of Biological Objects

IN a recent paper Ruska demonstrated experimentally the possibility of surpassing considerably the resolving power of an ordinary microscope by the use of an electron microscope This high resolving power cannot be applied in biological research however without developing a new histological technique to prevent the destruction of the organic cells by the intense electronic bombardment

To overcome this difficulty it seems that there are the following possibilities

(1) Intense cooling of the object (for example by contact with an extremely thin metal foil which is cooled by conduction)
(2) Impregnating the object with a substance which makes the object less destructible
(3) Impregnating the object in such a way that a framework of the object is preserved although the object itself is destroyed
(4) Combining methods (1) and (2) or (1) and (3)

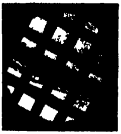

FIG 1 × 65

We obtained the best results by using the third method To arrive at good results by this method the following conditions must be satisfied by the metallic or other framework It must be (*a*) geometrically similar to the object (*b*) of high melting point and good thermal conductivity and (*c*) of high atomic weight

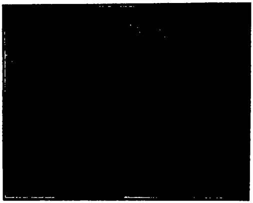

FIG 2 × about 450

Figs 1 and 2 show the results we obtained They represent a 15 μ section of a *Drosera intermedia* leaf on a copper net Fig 1 is enlarged 65 times and Fig 2 about 450 times The resolving power can be estimated from the sharpness of the border of the copper wire it corresponds to about 1 μ The microscopic object was impregnated with osmium as is done in the usual microscopy From the above photographs it seems that the osmium impregnation method can be applied—perhaps with some modifications—to electron microscopy

The photomicrographs were taken with an electron microscope of the magnetic type the description of which will be published later

Strength of Metal Single Crystals

In the course of some experimental work on single crystals of cadmium, which I have been carrying out under Prof E N da C Andrade, I have found that the condition of the surface exercises a surprisingly large effect on the initial strength of the crystal It is well known that glide commences in a single crystal when the shear stress on the glide plane, and in the glide direction, reaches a certain value known as the critical shear stress Thus in a series of crystals grown from cadmium (glide plane, hexagonal base, glide direction, axis of digonal symmetry), which proved to contain 0 15 per cent of lead and 0 15 per cent of zinc, this critical shear stress lay within the comparatively narrow range of 50–59 gm wt per sq mm, while the angles which the hexagonal planes made with the axis of the wire varied from 8° to 72°

When the crystals are grown in the presence of oxygen, there is a marked increase in the resistance to shear, values as high as 120 gm wt per sq mm being obtained As neither nitrogen, carbon dioxide nor water vapour produces a similar effect, the increased resistance to shear is attributed to a film of oxide formed on the surface of the metal Oxidation of the wires subsequent to their conversion into single crystals has the same effect, and even keeping the wires in a damp atmosphere at room temperature for several weeks produces a measurable effect Removal of the oxide film by brushing the surface with dilute sulphuric acid reduces the critical shear stress to the normal value of about 60 gm wt per sq mm

The effect cannot be attributed to any strength of the oxide film, since, first, there are considerations to show that it can only be a few atoms thick, and, secondly, there is a growth of the resistance to shear as deformation proceeds, and not the weakening which must ensue on rupture of the oxide film if its tensile strength were in question

To eliminate the effect of impurities, and of surface film, cadmium was carefully purified by sublimation *in vacuo*, which left no lead that could be detected and less than 0 1 per cent of zinc, and oxide free crystals were grown from it A single crystal prepared in this way showed a critical shear stress of only 13 7 gm wt per sq mm This seems to confirm the hypothesis of Haase and Schmidt[1] that crystals of perfectly pure metal would be unable to withstand even the smallest shear stress It may be noted that A W Hanson[2] has just published some results for very pure zinc, which bring the critical shear stress down to 9 1 gm wt per sq mm, but he does not refer to any influence of surface factors

It seems clear, then, that the ideal metal lattice has very little or no strength, slip starting at the surface and proceeding inwards, and that surface films of a certain character can prevent initiation of slip, and so greatly strengthen the crystal The analogy offered by the behaviour of rock salt, where the surface is of such significance, as evidenced by the behaviour under water, will readily occur

Zostera Disease on the Coast of County Cork, I.F.S

In view of the widespread effects of *Zostera* (sea grass and eel-grass) disease and the interest which it has aroused, the following brief note appears to be worthy of publication *Zostera* was first noticed to be affected by some sort of trouble in Castle Haven during the summer of 1932, when the extensive meadows near and north of Castletownshend were much less luxuriant than usual (Just off Castletownshend the plants are usually extremely robust and of great length) By the summer of 1933 the meadows had vanished At Lough Ine the various beds were unaffected until late in 1933 By December those in fairly deep water between the Coosh and the mainland, in the southern region of Barloge Creek and the two large meadows in Southern's Bay just below the Rapids, which are exposed at very low water, were very worn in appearance By the middle of February this year they had disappeared as had those which formerly all but covered the floor of the inner part of the Goleen, except for their dead remains At the end of March it was found that a further bed had completely disappeared from the Ballyally side of the Coosh By this time new growth had started in the Goleen and very soon became vigorous, whilst by the end of April there was strong growth over large areas in Barloge Creek, but no sign of any in Southern's Bay

Three chief points of interest emerge from these observations the disease seems to be spreading very slowly along the south coast of Ireland, having taken two years to travel the six miles which separate Castle Haven from Barloge Creek recovery has been extremely rapid *Z marina*, *Z nana* and the hybrid were equally affected and have made equally rapid recoveries All three occur in the Goleen, *marina* alone in the other localities I am told that at Castle Haven there has been no recovery but a simultaneous decrease in flatfish

Control of Chromatophores in *Leander serratus*

The phenomena of colour-change in prawns are well known[1,2], and the mechanisms controlling these phenomena understood in the main[2,3] Certain details, however, require further explanation, and among them are the following —

It is stated[3] that for *Palæmonetes varians*, a form very similar to *Leander*, the effect of (*a*) darkness and (*b*) light on a white background, is the same, red and yellow chromatophores contract and reflecting yellow chromatophores expand The reverse condition is produced by light on a dark background

I find that in *Leander*, conditions (*a*) and (*b*) produce similar but not identical effects The reflecting yellow chromatophores, fairly numerous in *Leander*, do not expand and contract automatically in a reverse direction to red and yellow types (which are under hormone control) but behave independently and according to light intensity Thus, irrespective of the background, they expand in good light and contract in dim light or in darkness They also continue to do this in eyeless animals where the red and yellow chromatophores are no longer under control. It is already known[2,4] that in certain

Crustacea there is a primary direct action of light on the chromatophores as well as a secondary action through the eyes, and this primary action undoubtedly plays a part in the colour-change of *Leander*

A further difference shown by animals in conditions (*a*) and (*b*) respectively lies in the behaviour of the deep seated chromatophores In light these are expanded, so that the course of nerve cord and dorsal blood-vessel, round which many are located, can be plainly seen, and the animal appears translucent In darkness these chromatophores are contracted, and the animal appears opaque

Again, there is a very marked difference in the position of eye pigments in animals in conditions (*a*) and (*b*) In darkness the eye looks black and has an enormous pupil in light on a white background it shows a black core and pale margin, while in light on a dark background it looks black all over and shows no pupil

Thus darkness, and light combined with white background, produce different results on the eyes and on certain of the chromatophores of *Leander* Light, however, is not the only factor that can affect the chromatophores, for a considerable expansion of red and yellow types may result from excitement or muscular activity

Occurrence of an Enteropneust in Wales

A SMALL Enteropneust was found by us while shore collecting on the Anglesey coast of the Menai Straits at the beginning of April 1934 Since then we have obtained a number of specimens from this locality. The animals live in clean sand near the low water mark of spring tides at depths down to nine inches They were found in association with ***Arenicola marina***, ***Ensis ensis***, ***Echinocardium cordatum*** and ***Ammodytes***

Its identification as a species of *Dolichoglossus* is justified by the absence of an appendix to the stomochord, of synapticulæ between the gill bars, of genital wings and liver diverticulæ, and the presence of a well-developed ventral non branchial part of the pharynx, of relatively large ova in the ovaries of female specimens, of an elongated proboscis and of a single proboscis pore on the left side

The records of occurrence of adult Enteropneusts around the coasts of the British Islands are few, although there is a number of records of the occurrence of *Tornaria* larvæ A fragment of a large *Balanoglossus* sp was obtained in 1900 on the Galway coast and Tattersall obtained several specimens of a species of *Dolichoglossus*, which he named *D ruber*, near extreme low tide mark off Coastguard Point, Ballynakill Harbour, Co Galway[1] Assheton[2] obtained specimens of *Dolichoglossus* in the littoral zone at Aros in the Sound of Mull, off the west coast of Scotland in 1907, which proved to be a new species, *D serpentinus* Since then Meek[3] has recorded a single specimen of *Glossobalanus*, dredged near the Farne Islands, off the coast of Northumberland, which he named *G marginatus* So far as we are aware this is the first record of the occurrence of adult Enteropneusts on the coast of Wales and the fifth for the British Isles

Although our specimens appear to differ in coloration from *D ruber*, Tattersall, and in external proportions from *D serpentinus*, Assheton, some time must elapse before we can determine whether it belongs to either of these species So far, the internal anatomy of neither *D ruber* nor *D serpentinus* has been described in detail

The Theory of Two Factors versus the Sampling Theory of Mental Ability

DR WILLIAM BROWN has published in NATURE of May 12 a communication on 'The Theory of Two Factors versus the Sampling Theory of Mental Ability" The matter is too involved to be discussed adequately in a letter, but I wish to record that I do not agree that this otherwise very valuable experiment is an *experimentum crucis* between my views and those of Prof Spearman, partly because I do not think Dr Mackie's formulæ are applicable in this way, but mainly because the tetrad differences had been trimmed down to the narrow scatter shown, by the choice of tests, by the rejection of one of those originally chosen, by the rejection of one of the remaining correlation coefficients, and by the elimination by partial correlation of a large group factor It is not in dispute that by these means a set of tests can be arrived at which give zero tetrads within the limits of sampling error and can then be described by a parameter *g* and as many parameters *s* as there are tests I would like to add that I admire and value the work done by Dr Brown and Dr Stephenson in arriving at the present series of tests

Distribution of Separates of Certain Papers by the late Dr. Bashford Dean

THERE have been placed in my hands, by Mrs Bashford Dean, for distribution among students of fishes, certain reprints of Dr Dean's studies on the archaic fishes, found among his effects after his untimely death

If research men who are interested in the morphology, anatomy and embryology of the cyclostomes, sharks and ganoids will go through Dr Dean's bibliography either in vol 1 of the "Bibliography of Fishes" or in Art 1 of the Bashford Dean Memorial Volume, and will indicate to me what articles they desire, I will forward these so far as they are available

It may be some time before the actual sending out can be done, but I should like to have all requests in before the distribution is begun.

Research Items

Bride-Wealth in a Tanganyika Tribe The function of bride wealth, the handing over of property to the parents of the bride, among the Wabena of the Ulanga Valley is discussed by A T and G M Culwick in *Africa*, 7, No 2 The manner of complying with the custom is subject to wide variation, which suggests that features belonging to mother right and father right exist side by side In former days, bride wealth consisted of three hoes, which were then of much greater value than they are now Each hoe was regarded as a separate payment, and ful filled a special function The presentation of the first hoe took place after arrangements for the betrothal had been made by an intermediary The man then built a hut for himself and his bride near her father for whom he was expected to work This payment did not constitute a binding contract, but the arrangement was confirmed by the payment of the second hoe It could not then be set aside on the girl's part without reason, but until she had borne a child, the husband could send her back to her father if he wished In this event, if his reason were not good, the father might not return the two hoes The husband still remained under the control of his father in law's family after the second payment, and was not emancipated from it until the payment of the third hoe had been made Even then he continued to render the family certain services and could not live more than a few miles away without their approval Although a man had much greater power over his children when the payment was complete, they continued to render greater respect to their mother's brother than to their father The custom has been much modified in recent times by economic causes, which have increased the amount payable and given the husband greater freedom from the control of the bride's family

Rock-Engravings in Tripolitania. Some of the results of a recent journey of archæological exploration in Tripolitania are described by Paolo Graziosi in *L'Anthropologie* **44** No 1–2 Until last year when two expeditions were at work, one being led by Dr L Frobenius, little was known of the rock engravings of Fezzan and nothing of the stone age industries of that area The oasis of Brach was made the head quarters of the Italian expedition, but for Wadi el Agial, Oubari served as the base In the neighbourhood of Wadi Marail, near Hamada el Homra, engravings of Bovidæ were found, of which one bore a spheroid between its horns indubitable sign of Egyptian influence One of the drawings appeared to be a rhinoceros, but was probably a badly-drawn member of the Bovidæ Two large figures of ostriches were found near El Gheriat In style these recall the oldest engravings of southern Oran Two areas which proved very rich were the Wadis Zigza and Massauda At the former the superimposition of engravings made a relative chronology possible which could be equated with variation in patina, style and technique The most ancient engravings showed giraffes in a fine naturalistic style The lines were deeply engraved and highly patinated Similar figures at Djebel el Ouenat have been demonstrated by the Abbé Breuil to be related to Bushman drawings Another group of later date shows an antelope, an aurochs and a number of Bovidæ in profile, but with the horns represented as if seen from above A third large group is composed entirely of domestic animals Here also is a human figure in a crouching attitude, which to a certain degree recalls South African art, but also has undoubted Egyptian affinities Among the latest engravings, but still anterior to the camel' period, are a number of vehicles drawn by horses and driven by men At Massauda were many rock shelters with engravings Among the most ancient, special mention is made of an elephant hunt, in which three elephants face two men armed with bows A third man lies on the ground, while others are under the animals The most numerous groups are of domestic animals and men some ithyphallic

Investigations in a Japanese Lake S Yoshimura has recently described his researches into the biology physiography, physics and chemistry of a small mountain lake near the Japan Sea (' Limnological Reconnaissance of Lake Busyû, Hukui, Japan " *Sci Rep Tokyo Bunrika Daigaku*, C, No 1, vol 1, 1932) An attempt was made by the Hukui Fisheries Station to utilise this lake for the culture of cold water fishes Lake Busyû which is elongated from north to south with its basin in the form of a pail, lies in a deep and narrow valley, the river entering from the south and flowing out at the north to enter the Japan Sea The water is very turbid greenish brown from the suspension of silt particles, and with no vegetation on the shores owing to the fluctuations in water level The surface is very hot and the bottom very cold the water weakly acidic, the surface water slightly supersaturated with dissolved oxygen, not due to the assimilation of the phytoplankton but to the sudden rise of water temperature in this layer which is exposed to the surface by the sinking of water level towards the summer The stratification of oxygen is very complex, which is an unusual feature in Japanese lakes There is no specially deep hollow but the shallow bottom is so steeply inclined that it cannot retain fine deposits What deposit there is is not decomposed mud but detritus of leaves and land plants The lake is regarded by the author as of the rich oligotrophic type The organic life consists of diatoms rotifers cladocerans and copepods in the plankton, several fishes in the nekton and in the benthos *Tubifex* at the bottom in great abundance (16–20 metres), *Endochironomus* dominant at 10–15 metres and a few *Tanypus* and *Chironomus plumosus* in the shallow bottom Fishes such as *Salvelinus* and *Coregonus* transplanted to the lake can survive

Isopods from the "Discovery" Expedition. Miss Edith M Sheppard, in her monograph on the family Serolidæ (Isopod Crustacea, Part 1, "Discovery Reports", vol 7, 1933) not only describes the collection made by the R R S *Discovery II*, the R.R.S *William Scoresby* and the staff of the Marine Biological Station of South Georgia during the years 1925–32, which is the most complete ever made both of species and specimens, but also gives a revised account of the genus *Serolis* with diagnostic characters of all known species, together with notes on their geographical distribution and general morphology Seven of the "Discovery" species are new to science, and of the fifteen shallow water species (excluding two which are doubtful) previously recorded from these waters, all except three have again been found' The genus, with the exception of one species recorded from San Diego, California, is entirely restricted to the southern hemisphere Most of the species are confined to shallow water and the deep sea forms are comparatively few in number but have a much wider vertical as well as horizontal distribution The species fall into four groups (1) outside the antarctic convergence, (2) inside the antarctic convergence, (3) round the shores of Kerguelen Island, Crozet Island, Marion Island and Prince Edward Island, (4) off the shores of South and East Australia From analysis of the adult females in the present collection the author finds that breeding goes on throughout the year, and that the number of females in the non breeding condition is comparatively small

Microsynangia of the Medulloseæ Under the title The Structure of Certain Fossil Spore Bearing Organs believed to belong to Pteridosperms , Prof Halle (*Kungl Svenska Vet Akad Handl*, Bd 12, No 6) makes a valuable contribution to our knowledge of the microsynangia of several genera attributed to the Medulloseæ A new group, Whittleseyinæ, based on the microsynangia, is proposed under which name are united several late Palæozoic spore producing organs characterised by very long tubular sporangia, an unusually strong vegetative development of the synangium and unusually large spores *Goldenbergia*, nov gen , hitherto believed to be a seed of the genus *Rhabdocarpus*, is now shown to be a large synangium formed of 12–16 tubular sporangia arranged in a single whorl enclosing a central cavity, whilst the supposed leaves or pinnules of *Whittleseya elegans* are shown to be cupule like synangia campanulate in shape and formed of very long tubular sporangia *Boulaya*, *Aulacotheca*, nov gen (*Holcospermum*), *Codonotheca* and *Dolerotheca*, nov gen (*Dolerophyllum*) are referred to this group The genus *Potoniea* is treated as the type of a second group, recalling the Whittleseyinæ but differing in structure and in the size and type of the spores In *P adiantiformis* and *P* (*Neuropteris*) *Carpentieri*, the probably free sporangia are shown to be long and tubular and to radiate from the bottom of the low, wide cup, which seems to be formed by a pinnule, the fructification being superficially likened to the capitulum of a composite *Zeilleria fructifications* are also shown to be synangia of the Whittleseyinæ type, though there is no evidence that this genus belongs to the Pteridosperms

Origin of Cultivated Tobacco The origin of cultivated tobacco, *Nicotiana Tabacum*, is a problem of considerable genetic interest In 1927, Clausen put forward the hypothesis that it was derived from a hybrid of *N sylvestris* and *N tomentosa* in which the chromosome number had been doubled This was based upon the fact that (1) *N Tabacum* has $n = 24$ chromosomes, while in the other two species $n = 12$, (2) when either of these species is crossed with *N Tabacum* the F_1 hybrids show $12_{II} + 12_{I}$ chromosomes in meiosis, indicating that each had a haploid set homologous with 12 of the *Tabacum* chromosomes Dr. D Kostoff (*Bull Appl Bot*, Ser 2, No 5, 1933) has recently reported upon extensive crosses involving these three species and also *N Rusbyi*, a woody-stemmed species nearest *N tomentosa* He points out difficulties with the above hypothesis, based partly on the absence of woody varieties of *Tabacum*, partly on the fact that many varieties of tobacco have pink flowers, while those of *N sylvestris* are white and those of *tomentosa* and *Rusbyi* rose green, and partly on the chromosome behaviour in the various hybrids Brieger has also argued against Clausen's hypothesis on the basis of similar experiments Kostoff produced the triple fertile species hybrid *N Tabacum* × (*N sylvestris* × *N Rusbyi*) which he calls *N triplex*, this appears to have originated from an egg cell of tobacco (with 24 chromosomes) meeting a male nucleus having 12 *sylvestris* and 12 *Rusbyi* chromosomes The hybrid thus has a complete haploid set of all three species and combines all their characters It is, moreover, cytologically balanced and produces normal gametes Nevertheless, it shows variations, and from numerous cytogenetic studies of its hybrids the conclusion is reached that while tobacco did not arise from the present *sylvestris* and *tomentosa*, yet it probably was derived from related forms which perhaps no longer exist

Winter Pruning of Apple Trees The practice of pruning was devised long before the opening of the Christian era yet it is only in recent times that an attempt has been made to understand the fundamentals of the process Hatton, Grubb and Amos, working at the East Malling Research Station, began experiments, and issued an early report in 1923 Their work has been continued by Dr R C Knight, who has recently published a further paper ("The Influence of Winter Stem Pruning on Subsequent Stem and Root Development in the Apple", *J Pom and Hort Sci*, 12, No 1, 1–14, March 1934) The earlier results are confirmed by improved experiments on more than five hundred trees of several varieties and grafted upon different rootstocks Winter pruning decreases the production of new roots, but increases shoot formation, though often at the expense of radial thickening There is, indeed, a decrease in the total amount of shoot growth, considered as extension growth plus increase in girth, and the relation of new shoot growth to new root growth is remarkably constant No influence of stem pruning on the type of root system was found The practical point, that it is better to prune immediately after planting if extension growth is required, emerges from a consideration of the results

Condensation of Water in the Atmosphere M G Bennett has reviewed (*Quart J Roy Met Soc*, Jan 1934) the present state of our knowledge in regard to the condensation of water in the atmosphere, the theory of which is found to be very much more complex than was formerly supposed Measurements of the sizes of droplets in fog and cloud made independently by several observers within the last thirty years, and especially within the last three or four years, are commonly held to suggest that the masses of the droplets are integral multiples of one of two standard minimum sizes, which appears to imply that the production of the larger drops takes place by the union of the smaller drops and not by their continuous gradual growth by condensation It was found further that the concentrations of chlorides in the droplets were integral multiples of the smallest concentrations ever observed It might be supposed that some very simple account of the process of drop formation could be based on these observations, but according to Bennett, any such account is incomplete Another difficult problem is the question whether a cloud or fog which is not subjected to changes of relative humidity is stable or whether it will tend to coagulate into larger drops. The electric charges carried by the droplets affect their vapour pressure slightly according to a relationship worked out by J. J. Thomson, the radius of curvature of the drops and the surface tension of the liquid being among the additional controlling factors, but the effect on the vapour pressure of the charges that have been measured is extremely small in the case of droplets as small as those in a fog; such charges may, however, affect the rate of coagulation of the droplets into drops. It is evident that the parts played both by the electrical charges and by the relative humidity in the growth and coagulation of drops in cloud and fog remain to be discovered.

Scattering of Hard X-Rays. A number of formulæ have from time to time been used for the intensity of the Compton scattering of hard X-rays, in particular one derived by Klein and Nishina on relativistic quantum mechanics. J. Read and C. C. Lauritsen (*Phys. Rev.*, April 1) have tested this formula experimentally using a high potential X-ray tube and a crystal spectrometer. The absorption per electron was measured in carbon and aluminium over a wave-length range of 20–50 X units (250–600 kv.). Over this range, the photoelectric absorption by the electrons is small and nuclear absorption is not to be expected, while the Klein–Nishina result differs appreciably from those given by the older theories. The experiment shows that the Klein–Nishina formula probably gives the correct scattering coefficient within one per cent over this wave-length range.

Fine Structure of X-Ray Absorption Edges. It is well known that when X-rays are absorbed by a solid, the short wave side of the absorption edge shows in general a pattern of maxima and minima. According to a theory of Kronig the electron extracted from the atom may only move through the periodic field of the lattice with certain discrete energies, the forbidden energies corresponding to Bragg reflections of the electron waves. This effect must be integrated to allow for the motion of electrons in all directions through the lattice. The theory is confirmed by investigations of the absorption edges of nickel, iron and chromium in the pure metals and in alloys of gradually varying lattice constant. D. Coster and G. Klamer (*Physica*, January) have investigated the fine structure of the potassium and chlorine *K* edges in potassium chloride crystals, using a vacuum spectrograph. The fine structures observed with these two elements were totally dissimilar, and if Kronig's view of the effect is to be applied to ionic crystal lattices, it seems that the rules which govern the transitions of the *K* electrons to the crystal lattice are quite different in the case of the Cl^- ion and the K^+ ion.

Optical Isomerism of the Menthols and Menthylamines. Prof. J. Read and Mr. W. J. Grubb have now described (*J. Chem. Soc.*, March) the isolation and characterisation of "the last of the menthols", namely, *d-neo-iso*-menthol, thus bringing to a successful conclusion a brilliant series of researches carried out by Prof. Read and his colleagues upon the highly complex group of menthylamines and menthols, all the stereoisomerides of which have now been isolated and characterised. Some idea of the formidable nature of the problem involved will be formed when one realises that the *cis-trans* isomerism of the parent menthone molecule is complicated not only by the asymmetry of two dissimilar carbon atoms at the points of attachment of the methyl and isopropyl groups but also by the development of a third 'centre of asymmetry' at the position of the original keto group. Thus menthylamine and menthol each give rise to eight optically active isomers, of which only four are needed for complete characterisation. In addition, there are the corresponding inactive *dl* forms to be considered. Comparison of the optical rotatory powers of the various compounds of the whole group reveals a complete parallelism between the amines and the alcohols, thus showing that the four sets of compounds are stereochemically analogous, although the relative molecular configurations are not yet to be regarded as finally settled. This work forms a valuable contribution to the study of stereochemical problems.

Propane-treated Automobile Oil. Science Service, Washington, D.C., has recently issued a Mail Report describing a new method of production of lubricating oil. Propane, as a liquified natural gas, is mixed with asphaltic base petroleum. The two liquids separate out into two layers, but not until the propane has extracted the desirable components from the asphaltic layer. The propane layer is then recovered with nitrobenzene, which cleans it from traces of remaining asphalt, and the lubricant is finally obtained by evaporation of the propane solution. Oil equal, if not superior, to Pennsylvania oil as at present refined can be produced in this way from cheap western oil. Proof of its efficiency is furnished by the results of stringent practical tests. Cylinder tops, lubricated with propane-treated oil, after 60,000 miles of high-speed duty, were less than one thousandth of an inch out of the perfect circle. Normally, under similar strain the tops would have been deformed into an oval shape. Comparatively easy production and efficient performance of such oil under test have done much to discount alarm caused by threatened exhaustion of good Pennsylvanian oil, since Texas, Oklahoma and California are now in a position equally with Pennsylvania to meet the demand for this product.

Colour Temperatures of Stars. In the *Observatory* of May appears an account of a paper by Messrs. Greaves, Davidson and Martin, to appear shortly in the *Monthly Notices of the Royal Astronomical Society*, describing a revision of the fundamental scale of colour temperatures which the authors have worked out at Greenwich. They have improved their photometric technique, but the change in the temperature scale is primarily due to a general revision of laboratory standards of colour. The temperatures which these authors actually find are very noteworthy, as they are markedly higher than previous estimates of colour temperature and ionisation temperature. For example, the Greenwich temperature for the mean *A0* star is now 18,000°—to be compared with 11,000° quoted by Russell, Dugan and Stewart ("Astronomy", Ginn and Co., New York, 1927). The Greenwich work comes on top of some recent observations which indicate that the colour temperature of the sun is about 6,800°, that is to say, definitely higher than the effective temperature, 5,740°. The Greenwich workers find 6,800° for the mean colour temperature of a number of *G0* stars.

Chemical Syntheses under Pressure

BY invitation of the president Prof G T Morgan, an ordinary scientific meeting of the Chemical Society was held at the Chemical Research Laboratory on Thursday, June 7, when three papers were contributed illustrating recent researches in the Laboratory on syntheses of organic substances under pressure

Mr R Taylor described the circulatory plant (afterwards seen in operation) employed in studying condensations between carbon monoxide and hydrogen at 400° and under 250 atmospheres in the presence of various catalysts with a rate of circulation of about 80 litres of compressed gas per hour In these researches, attention has been directed specially to the production of alcohols other than methyl alcohol (methanol) With a catalyst consisting of cobalt sulphide mixed with oxides of copper and manganese, an optimum yield of ethyl alcohol was obtained although this synthesis was always accompanied by large amounts of methane Systematic fractionation showed that more than ninety per cent of a product (b p 783°) consisted of alcohols with unbranched chains among which *n* hexyl and *n* heptyl alcohols were identified Branched chain products were represented by *iso*butyl alcohol 2 methylbutanol and 2 methylpentanol A manganese chromium catalyst strongly alkalised by rubidia gave a product in which all alcohols identified above the C_3 compound had branched chains Another catalyst containing cobalt and strong alkali gave a mixture of branched and straight chain alcohols

The chemical reactions involved in these syntheses were discussed and successive aldolisation and hydrogenation were suggested as the directive mechanism For straight chain alcohols acetaldehyde (a product actually identified in these condensations) must be present to provide the active hydrogen for aldolisation, and its condensation with propaldehyde would eventually lead to *n* amyl alcohol When propaldehyde furnishes the active hydrogen the final product is 2 methylpentanol It may become possible to build up alcohols with a predetermined number of carbon atoms

Dr D V N Hardy indicated an alternative mechanism by which it is supposed that carbon monoxide is added directly to alcohols with production of acids, which may then be reduced to aldehydes and alcohols The condensations between methyl alcohol and carbon monoxide have been studied at 320° 340° under a pressure of 150 atmospheres in the presence of phosphoric acid The gas was circulated at a rate of 2 cubic metres per hour, and 120 gm of methyl alcohol vapour was introduced into the system during the same period Acetic acid and methyl acetate were obtained, together with an oily layer containing high boiling hydrocarbons from which hexamethyl benzene was isolated When 2 per cent by weight of copper phosphate was added to the phosphoric acid, this oily layer was no longer formed and larger proportions of acetic acid and its methyl ester were obtained Some dimethyl ether was identified but as it did not accumulate in the system it may be regarded as a reagent These experiments favour the view that a methylene radical is produced which unites with carbon monoxide to form ketene, this reactive compound being then hydrated and methylated to acetic acid and methyl acetate respectively

Dr D D Pratt discussed the use made of autoclaves in practically all research sections of the Laboratory These autoclaves which have been constructed in the laboratory workshop have capacities ranging from 50 c c to 10 litres, they are capable of withstanding pressures of 200 atmospheres at temperatures up to 450

Phenols aromatic hydrocarbons and bases undergo carboxylation when condensed with carbon dioxide under pressure in presence of catalysts such as aluminium and zinc chlorides

High pressure aminations of alcohols and phenols have led to significant results Resorcinol and orcinol heated to 200° with aqueous ammonia give rise to *m* aminophenol and 5 amino *m* cresol respectively In similar circumstances resorcinol and ethylamine furnish *m* ethylaminophenol an important colour intermediate

Autoclave experiments have been made on the reactions between hydroxylic compounds and ammonium chloride At 300° ethyl alcohol gives a mixture of mono di and tri ethylamines separated by fractionation through a Dufton column At 320°–350° phenols are converted into a mixture of primary and secondary amines This amination which is particularly successful with *m* cresol and symmetrical xylenol is of technical importance, since the resulting *m* toluidine and 1 3 5 xylidine are not readily obtained by successive nitration and reduction from toluene and *m* xylene In these aminations of phenolic homologues the effect of orientation in the aromatic nucleus is plainly discernible In the diphenyl series the ammonium chloride reaction on 2 hydroxydiphenyl and 2 2′ dihydroxydiphenyl leads respectively to *o* xenylamine and carbazole, another important colour intermediate

At the conclusion of the meeting the visitors were conducted through the laboratories in which exhibits and demonstrations had been arranged illustrating the following researches —

Synthetic production of methyl and other alcohols from carbon monoxide and hydrogen and the synthesis of acetic acid from methyl alcohol and carbon monoxide For the characterisation of higher aldehydes and alcohols it is necessary to have authentic specimens of well-crystallised derivatives, and a collection of these products was on view

In the tar section there were demonstrations of shirlacrol a new wetting agent used in mercerising cotton and of the extraction of catechol and resorcinol from industrial liquors The identification of tar constituents involves the synthesis of higher phenols and complex aromatic hydrocarbons Distinctive specimens of such products were exhibited together with fuel oils derived from the hydrogenation of tars In the road tar section a large scale plant for the separation of the crystalloid and resinoid constituents of tars was in actual operation

The allied sections of chemotherapy and synthetic resins were illustrated by comprehensive collections

Inorganic chemistry was represented by researches on the aerial and immersed corrosion of metals, the production of base exchange materials from English clays and the isolation of rarer metals such as germanium and rhenium from British minerals The exhibits arranged by the microbiological and dental investigation sections were also greatly appreciated by the visitors, who numbered about 260

New Regulations for the Natural Sciences Tripos

THE Committee of the Natural Sciences Tripos at Cambridge has issued a report on the regulations for that Tripos The changes suggested in Part I are consequential on the recommendations of the Syndicate on Medical Courses and Examinations New half subjects are introduced in biochemistry, physical and inorganic chemistry, organic chemistry, pathology and zoology (mathematics is already a half subject) Every candidate must take at least three whole subjects or at least two whole subjects and two half subjects

Anatomy (a whole subject) is to consist of approximately equal proportions of topographical anatomy and scientific anatomy (embryology and morphology) A broad, rather than a detailed, knowledge of topographical anatomy will be required The questions will deal mainly with the general architecture of the body and will not require a detailed knowledge, except of the more important areas In the papers on physiology there are to be some optional questions on pharmacology, but it will be possible to obtain full marks in physiology without attempting any questions in pharmacology

The half subject pathology is to be treated from the point of view of abnormal biology and is to include the variations which may occur in the structure and functions of living tissues and organs, together with the biology of parasites bacteria and viruses In the half subject biochemistry, a knowledge of the chemical processes associated with the normal life and growth of animal and vegetable organisms including micro organisms is required

In Part II, one of the four papers in geology and in mineralogy and petrology is to be common to both subjects Candidates in geology may substitute one of the papers in mineralogy for one of the papers in geology and vice versa Candidates in physiology may substitute for a specified paper in physiology a paper in pharmacology or for two specified papers in physiology two papers in experimental psychology

In Part II (chemistry), the first two papers will be of such a nature as to test the candidates' knowledge of general chemical science The third and fourth papers will be set so as to enable candidates to show a specialised knowledge of some of the subdivisions of chemistry They will include questions in inorganic, organic, theoretical and physical chemistry colloid science metallurgy, crystal chemistry; and candidates will be allowed complete freedom of choice in the questions which they attempt A sufficient number of questions will be set in each of the subdivisions for a candidate to attain the standard of the first class by answering questions in one or more of them

In Part II (physics) the first three papers will be of such a nature as to test the candidates general knowledge of physics The fourth paper will be of such a nature as to enable candidates to show a specialised knowledge of some branches of physics This will contain a large choice of questions so that it will not be necessary for a candidate to have a specialised knowledge of all branches of the subject This paper will include a sufficient number of questions on crystallography and crystal physics for a candidate to be able to gain full marks on the paper by answering questions on those branches only

---

Russian Studies of the Stratosphere*

PLANS for the ascent into the stratosphere in the U S S R were first made in December 1932, and after various preparations the actual ascent was made on September 30, 1933, by G A Prokofiev, K D Godunov and Birnbaum A height of nearly 19,000 metres was reached The Central Geophysical Observatory has now issued a report in Russian of the ascent

The original intention was to take measurements of the pressure and temperature of air intensity and hardness of cosmic rays, intensity of electric field conductivity of atmosphere, intensity of solar radiations, and analyses of the air, at various heights It was, however, decided that in order not to overburden the balloon with the weight of all the necessary apparatus, the measurements of the intensity of electric field and solar radiation, as well as the observations on the conductivity of air, were to be postponed to the subsequent ascents

The intensity of cosmic rays was measured by means of a Kolhörster electrometer, made of iron volume 4,200 cm ^{3} and electrostatic capacity 0 35 cm During the ascent, the electrometer was charged by means of an ebonite rod Measurements were made between the heights of 9,600 metres and 15,900 metres, the maximum possible error was estimated as 5 per cent The results obtained show fair agreement with Prof Piccard s observations but there is a discrepancy of more than 30 per cent with the results of Prof Regener

Prof Regener s observations		Prof Piccard s observations		Russian observations	
Pressure in mm Hg	Intensity of cosmic rays	Pressure in mm Hg	Intensity of cosmic rays	Pressure in mm Hg	Intensity of cosmic rays
	ions/cm ^{3}/sec		ions cm.^{3}/sec		ions/cm ^{3}/sec
150	153	142	215	137	221
100	224	127	248	86	345 3
75	243	88 5	305		
		83	313		

In order to measure the hardness of cosmic rays, a specially adapted Hesse electrometer was used, volume 1,100 cm ^{3}, electrostatic capacity 1 2 cm The electrometer was charged again by an ebonite rod, and was placed in a lead filter, with a wall thickness of 30 mm The first set of measurements was taken at the height of 17,500–17,900 metres, when the electrometer was covered by the lead filter on all sides The ionisation found was 338 ions per c c per sec, with a possible maximum error estimated at 8 per cent A second set of measurements was taken at the height of 17,400–17,900 metres, but with the lead lid of the filter taken off The ionisation found in this case was 415 ions per c c per sec , within a possible error of 5 per cent

---

* The Central Geophysical Observatory and the Ascent into the Stratosphere on September 30 1933 A collection of articles (in Russian) by various authors Pp 26 Leningrad 1934 1 rub

This series of results differs considerably from the results obtained by means of the Kolhörster electrometer (height 15,460 metres), and with the results obtained by Prof Piccard Unfortunately, no measurements were made with the Hesse electrometer completely out of the lead filter The excess of ionisation is considered by the author (A B Verigo) to be due to the secondary radiations arising in the zinc walls of the electrometer under the action of cosmic rays

Samples of air in the stratosphere were taken by means of specially constructed glass balloons suspended outside Precautions were made to prevent possible contamination by air or gases which might arise from the balloon itself The sample taking balloons were originally at high vacuum and were opened and sealed electrically Full descriptions of these small balloons are given

In order to prevent contamination, samples of air were only taken during descent or when the balloon was floating Analyses of the air samples were made independently by A V Moskvin in the Electrophysical Institute and by A A Tcherepennikov in the Gas Analysis Laboratory of the Central Geological Institute The following results were obtained

(1) Pressure inside the balloon after reducing to the original volume (1,120 c c) and to a temperature of − 55° C was 47 5 ± 2 mm mercury

(2) No hydrogen was found

(3) The percentage volume of oxygen was 20 95 at a height of 18,500 metres

(4) The contents of nitrogen and the sum of inert gases scarcely differ from the contents of air at the earth's surface

The results obtained were so unexpected that a suggestion had to be considered that, owing to some unforeseen circumstances the sample taking balloons were filled by air somewhere near the surface of earth This suggestion was disproved by measuring the humidity of air in the sampling balloons A mirror hygrometer was used At the temperature of liquid air no traces of moisture were found Parallel experiments on specially dried air from the earth s surface with water vapour contents estimated at 0 5, 0 1 and 0 02 mm mercury gave positive results on the same mirror This ruled out the possibility that the air in the glass sampling balloons was taken on the earth s surface, and the author (M I Golzman) suggests that there can be no doubt that the air in the sample balloons was taken in the stratosphere

The lowest temperature observed during the ascent was − 57° C Measurements were made by a platinum thermometer and Wheatstone bridge

The rest of the pamphlet gives descriptions of the various pieces of apparatus that were used during the ascent the way in which they were arranged inside the balloon and also of other equipment which was prepared but not used in order to avoid overburdening the balloon

---

Archæology of the Caucasus

THE late Prof Reginald W Fessenden author of The Deluged Civilization of the Caucasus (see NATURE, 113 317 March 1 1924) who had devoted forty years to the study of the prehistory of the Caucasus and had collected hundreds of thousands of references to the area, left much material still unpublished at the time of his death Additional chapters of his book and a number of collected papers have now been privately printed—unfortunately for purposes of reference, under the same title In these the author had put forward further applications of his theories which were based upon an intensive study of the mythology of ancient Egypt, Mesopotamia and Greece, of names, both personal and place names, and of ancient geography He again aimed at showing that there is evidence to support his view that not only was the Caucasus the land of the Book of the Dead, the original home of the Egyptians, the scene of ancient stories such as that of the labours of Hercules and the place of origin of Abraham , but also that it is the centre from which sprang all the great civilisations of antiquity, as well as the place of differentiation of the white and black races from a negrito stock

Prof Fessenden here also attacked the question of Atlantis and the Platonic numerical cipher of the 'Critias", as well as the Egyptian origin of masonry The author was neither an archæologist nor a philologist ; and in working out the identification of names of places and the interpretation of references in the traditions, he used material of very unequal value indiscriminately Yet his suggestions at times were remarkably acute His theories attached a significance to the Caucasian area which archæological research may well confirm, at least, in part

There has been a number of indications recently pointing to the importance of the Caucasus as an area for exploration in relation to the early prehistory of adjacent countries , while the richness of the country on the eastern side of the Caspian in evidences of antiquity has to be seen to be believed This must not be taken to endorse Prof Fessenden s belief that exploration with oil boring apparatus would bring to light the contemporary records of the pre diluvial period which he held according to tradition, had been buried in subterranean chambers Reference at the moment is opportune, as the time is ripe for action The Soviet Governments are willing, and indeed anxious to co operate with outside bodies in the work of anthropological research They have already approached the United States, and one joint expedition has been at work on an ancient Gothic site in the Crimea on behalf of the Academy of the History of Ancient Culture and the University of Pennsylvania Museum This expedition has enriched the latter institution to the extent of 3,600 objects, ranging in date from the historic period to 1500 B C The matter is not without urgency, as in certain areas the exploitation by the Government of material resources is a source of danger to the antiquities

In the northern Caucasus the construction of an immense hydro electric station will inundate a large area in which, it is estimated, in a year's time, some hundreds of burial mounds and tombs of the early bronze age and other archæological monuments of later date, belonging to the Scythic, Gothic or Tartar civilisations, will have been irreparably damaged or entirely destroyed. In order that something at least may be saved, the Soviet Academy for the History of Early Culture has again asked for the co-operation of the University of Pennsylvania Museum. As the level of the water has already been raised 19 ft. in the past year, it will be possible to save only a limited amount by excavation before next autumn, when the work is to be completed. Yet the value of the material which is thus being lost to archæological science is incalculable. Not merely has the north Caucasus been examined only very imperfectly but also the implications of the discoveries already made in this area are very little appreciated. On this point it is worth while to glance at a communication by Prof. V. L. Avdief of Moscow on the relations of the Caucasus and early Egypt, which appears in *Ancient Egypt and the East*, Pts. 1-2, 1933. Prof. Avdief points out that the most valuable evidence on the cultural relations of the Caucasus and the countries of the ancient East is to be expected from the monuments of the chalcolithic and bronze age cultures of the Koban type in the Euxine region. In the Ossetian and Kabarda Balkaria Autonomous Region of the North Caucasus, where the author conducted excavations in 1931-32, the bronze and chalcolithic cultures are well developed. Here there were extensive deposits of copper ore, which indeed are not yet exhausted. In prehistoric times the tribes constantly extracted and worked these ores. The numerous bronze objects recently discovered in that area present close resemblances to those found at Koban. For example, a small stone hatchet, possibly ceremonial, found near Nalchik, fairly polished, with a central bored hole and partly bent downward, resembles one found at Koban. The pottery with incised line decoration painted white, the representation of animals in bronze akin to the Koban 'animal style' and finally the mode of burial in stone cists exemplify the same relation.

Certain objects found at Balkaria show relationship with ancient Egyptian culture. One of the most striking is an anthropomorphic deity standing in the middle of a circle which may symbolise the sun. It is comparable to a representation of the god Bes or Pateka. Late Egyptian (Hellenistic or Roman) objects found in Balkaria prove cultural or commercial relations in the first millennium B.C., and these relations are shown by a number of objects of domestic purpose to have extended to Assyria and Babylonia, although the actual trade routes are difficult to establish.

Energy Relationships in Chemical Reactions

IN opening a discussion at the Royal Society on May 10 on the "Energy Distribution in Molecules in Relation to Chemical Reactions", Mr. C. N. Hinshelwood referred to some unimolecular reactions in which the velocity curve seems to be composed of several curves superposed, and suggested an interpretation in which several virtually independent reactions are taking place at the same time, all unimolecular and differing only in the values of the various characteristic constants. It is supposed that once a molecule has received its activation energy the internal rearrangement of this is relatively difficult, and according to the original way in which the energy was placed in the molecule there will be a different probability of chemical decomposition.

Investigations show that with certain substances molecules with activation energy differently located or distributed seem to behave as virtually independent entities for kinetic purposes; that there is a limited number of types of such molecules, and that the chance that activation energy is communicated to a molecule in such a way as to cause rapid decomposition is relatively much greater in substituted molecules such as C_6H_5CHO as compared with HCHO. Investigations in liquid systems seem to suggest that there are two extreme cases, in one of which the rate of reaction is primarily determined by the acquisition of the necessary activation energy, and in the second a probability factor independent of temperature is of equal or greater importance and the reaction velocity is many powers of ten smaller than the activation rate.

There is a suggestive connexion between this and the remarkable catalytic effect of solvents, often roughly parallel with their polarity, on one hand, and on the other hand with the fact that in reactions where one of the reactants is an ion, the rate is usually nearly equal to the activation rate, as though the great electrostatic forces contributed a perturbation powerful enough to increase the transformation probability to nearly unity.

Barking Power Station

THE new generating station of the County of London Electric Supply Co., Ltd., is situated at Barking on the bank of the River Thames about half a mile below Barking Creek. Its output is now 390,000 kilowatts, the largest in Britain, and when completed it will be about 600,000 kilowatts and will probably be the largest in Europe. It plays the leading part for the south-east England area in the Central Electricity Board's scheme. Ten circuits converge on Barking, six at 132 kilovolts and four at 66 kv. The Board's transforming station is situated on the opposite side of the road to the power station and is equipped with several very large high tension transformers.

The Company with its associated companies supply power over an area of about 3,000 square miles. It supplies four London boroughs and a large number of the inner suburbs. In addition, it supplies various districts in Surrey and Essex. The associated companies feed large parts of Kent and Sussex. It is also developing outer areas under various electrification schemes. According to *Distribution of Electricity* of February, published by Messrs. W. T. Henley's Telegraph Works, it is intended ultimately to provide a supply for each village or township in the area having a population of 500 or more persons. In addition, transmission lines along the route will in due course be tapped at any point where a demand exists There are now more than seventy towns and villages where electric supply is available There are several large poultry farms where electric hatcheries are in operation Farms also use the electric supply for fruit and vegetable canning and there are flour mills small water and sewerage schemes, gravel and sand pits brick making and timber yards and sawing mills where it is employed In addition to supplying electricity in bulk to many supply undertakings it also supplies for traction purposes the London Midland and Scottish Railway and the London Passenger Transport Board (Morden Tube)

The new extensions of the Barking power station work with a boiler pressure of 600 lb per sq inch The temperature of the steam is therefore about 800° F A few years ago it looked as if a still higher pressure would become the standard In America steam pressures of 1 200 lb per sq inch were first used, later pressures above 3 000 lb per sq inch were used in Europe Seeing that the new Battersea power station works at between 600 lb and 650 lb pressure and that the new Fulham station is being designed for this pressure it looks as if 650 lb would become the standard pressure It is interesting to remember that early steam boilers worked with pressures of about 8 lb

University and Educational Intelligence

CAMBRIDGE—The following appointments have been made—J H Driberg University lecturer in anthropology, Dr S Dickinson University lecturer in mycology in the Department of Agriculture W J Dowson (Christ s College) University lecturer in mycology in the Department of Botany and Dr H Godwin (Clare College) University lecturer in botany

The degree of M A *honoris causa* has been conferred on Sir Charles Martin formerly director of the Lister Institute of Preventive Medicine and professor of experimental pathology in the University of London

At Girton College Dr O Taussky and Dr C Leubuscher have been elected to research fellowships

On June 6 the following honorary degrees among others were conferred Sc D Prof Alfred Fowler Yarrow research professor of the Royal Society and professor of astrophysics in the Imperial College of Science Litt D Prof Samuel Alexander honorary professor of philosophy in the University of Manchester

LIVERPOOL—The Council of the University has accepted with regret the resignation of Mr R O Street senior lecturer in applied mathematics on his appointment to the chair of mathematics in the Royal Technical College Glasgow

The University of Berne has conferred the honorary degree of D Sc on Prof Share Jones director of veterinary studies and professor of veterinary anatomy in the University in recognition of his services to veterinary education and his distinction in his own branch of research

SHEFFIELD—The title of emeritus professor has been conferred on Prof Edward Mellanby formerly professor of pharmacology in the University

Science News a Century Ago

The Royal Society

At the meeting held on June 19, 1834 fourteen papers were taken, amongst those a paper submitted on borings and ravages in timber by William Thompson vice president of the Natural History Society of Belfast was widely reported at the time The opinion advanced that the *Teredo navalis* had ceased to be found on the British coast was shown by the author to be erroneous since numerous specimens had been collected from the piles used in the formation of the pier at Portpatrick in Ayrshire

The subjoined letter from Mr J G Children Sec R S addressed to Mr Francis Baily, vice president was read: British Museum June 19 1934 His Royal Highness the President requests that when you adjourn the meeting this evening to the 20th of November you will have the goodness to express his great regret that unfortunately the state of his health and sight has lately been such as to render it impossible for him to preside at the ordinary meetings of the Society so regularly as it was his anxious wish to have done His Royal Highness begs you will assure the Society that his absence has been occasioned by the cause alluded to alone and from no feeling of diminished interest in the prosperity of the Royal Society or of regard and respect for the Fellows on the contrary His Royal Highness hopes that by the blessing of Providence his health will soon be in all respects so far re established as to enable him on the reassembling of the Society to resume the chair and fill it with that uninterrupted regularity which it is His Royal Highness s most anxious wish to observe in whatever duty he undertakes PS His Royal Highness requests you will in his name bid the Fellows heartily farewell till he meets them again in November (*Proc R y Soc* vol 3)

Cause of the Aurora Borealis

A paper On the Nature and Origin of the Aurora Borealis by the Rev George Fisher read before the Royal Society on June 19 forms an excellent illustration of the state of geophysics in 1834 Arguing from the general fact that the Aurora Borealis is developed chiefly on the edge of the Frozen Sea or wherever there is a vast accumulation of ice the author concludes that it is an electrical phenomenon arising from the positive electricity of the atmosphere developed by the rapid condensation of the atmosphere in the act of freezing and the induced negative electricity of the surrounding portions of the atmosphere and that it is the immediate consequence of the restoration of the equilibrium by the intervention of the frozen particles which being imperfect conductors become luminous while transmitting this electricity In tropical and temperate climates this phenomenon does not occur because the electric equilibrium is restored by means of aqueous vapours, a process which often gives rise to thunder and lightning

Lardner on Babbage's Calculating Machine

A century ago few men of science were more widely known than Dr Dionysius Lardner (1793-1859) who from 1827 until 1840 held the chair of natural philosophy and astronomy in University College, London The writer of many textbooks he projected the Cabinet Cyclopaedia and secured for it the co operation of Herschel, Brewster, Powell and other distinguished men He was also well known as a lecturer, and on June 21, 1834, he lectured to a crowded audience in the theatre of the Mechanics' Institution on Babbage's calculating machine, to the cost of which the Government had contributed largely, but the construction of which was then at a standstill Lardner dealt with the history and the principles of calculating machines and referred to their importance for the construction of correct mathematical tables In its report of the lecture, the *Times* said that it would be considered a matter of national concern if means were withheld for the completion of Babbage's machine The occasion was rendered notable by the presence in the chair of Lord Brougham and the attendance of M A Dupin, the president of the French Chamber of Deputies, whom the Committee of Management elected an honorary member of the Institution M Dupin was the brother of Baron Charles Dupin (1784 1873), the mathematician who had written on the manufactures and industries of England In announcing M Dupin's election, Dr Birkbeck said he trusted, after what M Dupin had heard that evening, that he would be induced to continue to lend his powerful aid and assistance to his brother in promoting the establishment of similar institutions to their own in France

McCormick patents his Reaping Machine

There were many pioneers of the reaping machine but the outstanding inventor was Cyrus Hall McCormick (1809–84) His machine was exhibited at the Great Exhibition of 1837 and the *Times* said of it that 'if it fulfilled its promise, [it] was worth the whole cost of the Exhibition" McCormick was the son of Robert McCormick (1780–1846) of Walnut Grove" Farm, Virginia, a man of many interests who himself attempted but abandoned the task of constructing a reaping machine At the age of twenty two years, young McCormick, undaunted by his father's failures, took up the problem and in a year or two produced a machine which was tried with considerable success ' The fundamental principles in this reaper," a recent writer has said, the divider, reel, straight reciprocating knife, fingers or guard, main wheel and gearing, and front-side draft traction, together with their peculiar combination, have proved essential to reaping machinery down to the present time " McCormick, faced with a rival in Obed Hussey, patented his important invention on June 21, 1834 He spent several years in perfecting it, but finding difficulty in getting his machines constructed, in 1847 founded a works at Chicago, then a small lake side port By 1851 he was building 1 000 machines a year and in 1857 constructed 23,000 The firm he founded is now the International Harvester Company McCormick became very wealthy and many honours came to him, the Paris Academy of Sciences in 1879 electing him a foreign member "as having done more for agriculture than any other living man"

Magnetic Survey of the British Isles

In 1834 Capt (afterwards Sir Edward) Sabine commenced, in conjunction with the Rev. Humphrey Lloyd and Capt (afterwards Sir James) Ross, the first systematic magnetic survey ever made of the British Islands The results were published in a series of reports to the British Association, commencing 1835, and the first observations (apart from some preliminary tests of instruments) appear to have been made by Sabine at Limerick on June 21 1834 The British Association report for 1835 contains a "Magnetic Chart of Ireland A D 1835" In 1836 Sabine, almost single handed, extended the survey to Scotland and in 1837, with Lloyd, Ross and other collaborators, to England The recording plotting and combining of the observations to obtain the most probable mean results represent a very large undertaking

The Overland Route to India

At a meeting of the Royal Geographical Society held on June 23, 1834, presided over by John Barrow a paper was read "On the Manners of the Inhabitants of the Southern Coast of Arabia and Shores of the Red Sea, with Remarks on the Ancient and Modern Geography of that Quarter, and the Road through the Desert from Kosir to Kenah" This paper was communicated by James Bird, who had lately returned by that route from India Bird had made the passage from Bombay to Aden, and thence to Jeddah and Kosir by a steam packet, and the interest in his account was heightened by the project of steam navigation to India having just been made the subject for a public inquiry

Societies and Academies

London

Royal Society, June 7 G I TAYLOR (1) The mechanism of plastic deformation of crystals Plastic strain is chiefly due to the sliding of one plane of atoms over its immediate neighbour in such a way that the perfect crystal structure is re formed after each atomic jump Slipping occurs over limited lengths of the slip plane, and this type of plastic strain necessarily gives rise to elastic stresses near the two dislocations which occur at the two ends of each of these lengths The assumption that such dislocations will migrate through the crystal, owing perhaps to temperature agitation, under the influence of even the smallest shear stress, leads to a definite picture of the mechanics of plastic distortion (2) The strength of rock salt Experiment shows that plastic strain in rock salt is the main factor determining the strength of well annealed crystals A recent theory of the strength of metals is applied to rock salt and shown to lead to a parabolic relationship between tensile stress and plastic strain It is concluded that the strain in rock salt occurs in the crystalline parts of the structure where the crystal order is perfect, and that the strength is determined by the mean free path of the centres of dislocation The latter, which is of the order of 10^{-4} cm , is determined by the distance apart of the faults and by the temperature *The theory therefore assigns a definite function to the faults in determining the strength of crystals irrespective of their actual crystallographic or atomic nature* C A. BEEVERS and H LIPSON. The crystal structure of copper sulphate pentahydrate, $CuSO_4.5H_2O$ The copper atoms lie on the special positions (000) and $(\frac{1}{2}\frac{1}{2}0)$ and the sulphur upon the general position (0 01 0 29 0 64) *Four of the waters* are arranged in squares around the coppers, and two oxygens make with these approximate octahedra The fifth water is not co-ordinated, but is in contact with two oxygens and two waters All the waters show two oxygen bonds each, in accordance with recent ideas

Anthropological Method and Native Administration

FROM almost the earliest days of the scientific observation of peoples of backward culture it has been a commonplace of ethnographical literature to deplore the break up of custom under the impact of European civilisation This attitude of mind argues a certain confusion of thought It is unquestionable that the contact of an individualistic economic and social system such as that of Western culture with a native society in which the unitary character of the group whether of the family or tribe with its attendant aura of religious sanctions is paramount has rendered more difficult the task of the investigator of non European types of social institution and has caused the loss to science of data of high value for sociological studies but it has to be remembered that this very material of which the contamination is regretted does not probably in even a single instance represent a homogeneous or primitive cultural phase

The more intensive becomes the study of the character and make up of specific cultures the more apparent does it become that like the pure race in the classification of the varieties of mankind a primitive culture is an abstraction a logical postulate of sociological argument of which the material counterpart at this late date in the history of human development is never likely to meet the eye of the explorer Just as the existing races of mankind are the products of a long process of racial contact followed by opportunity for differential development so the forms of social organisation which have hitherto provided the subject matter of observation and record are the results of cultural contacts combinations of different strains of culture which have attained a certain measure of stability in a period of isolation partial or complete

The disintegration of native custom is no new thing In modern times it differs from previous manifestations of the effect of a clash of cultures whether inferred from cultural analysis or recorded in history only in the rapidity with which it is taking place and in the greater disparity of the conflicting elements Even the latter factor may be too strongly stressed It is indeed difficult to gauge the degree to which the present break up of custom is more intense than those of the past How great for example must have been the dislocation which resulted from the disparity in culture when a sedentary agricultural people of settled habits was overrun by a tribe of war-like nomad pastoralists. The results may be seen in the anomalous social groupings which followed on the Aryan invasion of India or the spread of pastoral peoples over agricultural Africa. As a more familiar, if less extreme, example may be taken the change in social and economic organisation which supervened on the incursion of the Saxons into a Britain the inhabitants of which had attained a nice adjustment of tribal life to their capabilities in exploiting the land, or had become partially urbanised.

Where there has been a default of written records, these and similar hybrid cultures have had, perforce, to be studied each as an integral complex. Their previous history has been purely a matter of inference. As time goes on, however, there is a steadily increasing number of peoples of whom it is possible to say that there are records to show that their culture is no longer as it was first seen or described by the white man. For example, a recent account of female initiation in an African tribe records evidence for no less than four modifications of ceremonial within living memory ("Valenge Women". By E. Dora Earthy. London, 1933.) The fact that the evidence for these modifications was afforded by native record does not affect the principle. For the present purpose the important point is that, so far as such cultural modifications may be regarded as corruptions of custom due to European contacts and therefore of negligible interest to the science of anthropology—as contrasted with forms of institution and belief recorded at the point of earliest contact—there is danger that the academic study of man may be divorced from actual conditions, to the detriment of the science as an aid in practical affairs.

For many years British anthropologists have urged that some knowledge of the principles of anthropological science is an essential element in the training of those who are to enter into official relations with the backward peoples of our dependencies, and a practical necessity in the successful administration of native affairs. Unfortunately, human nature is not cut to pattern and the application of general principles to cases in, let us say, the heat of conflict between custom and authority has proved on occasion by no means so simple a function of the spirit as it may have seemed in an academic atmosphere. As a matter of experience, it has been found that to think out, or to inquire into the implications of custom in the light of scientific principles, makes a greater demand on the time and the mental flexibility of an already heavily burdened official than it is possible always to meet.

Under the administrative system known as 'indirect rule' the knot has been cut, as indeed was inevitable to meet the needs of the situation by a direct record of law and custom as a working organism; but such a record, however strictly the collection of data has conformed to the canons of scientific method, in so far as it is 'particular', is the raw material of anthropological science rather than a contribution to the scientific study of man as such. Nothing is added to the interpretation of general principles for the use of the administrator outside the immediate sphere of reference. The indisputable scientific value of the official records from West Africa and New Guinea, in the form in which they have been given to the public, is due to the non-essential fact that the collection of the data has been entrusted to officials who happened also to be trained anthropologists.

The ultimate aim of indirect rule is too big a question to raise here. It must suffice to point out that, for the present purpose, it may be regarded as static and conservative. In other areas, in which methods of administration have developed out of a traditional native policy—too often, perhaps, a lack of policy—however much heed may now be given to the preservation of native custom making for stability, there has been a steady drift towards the disintegration of native modes of life. This was an inevitable result of the conditions of white settlement and the exploitation of tropical and sub-tropical lands. Further, in times of stress, native institutions are apt to be set on one side, even when the subject of a pledge, as happened, for example, in the instance of the Kakamega goldfields in Kenya.

In these circumstances, it must be patent that the academic study of the science of man—more particularly of man as a member of an organised society, the subject matter of social anthropology—tends in an increasing degree to lose touch with the everyday problems of native life and administration. In academic studies, material recorded thirty or forty years ago may, and in nine cases out of ten will, have a greater significance than the conditions of to-day. For the administrator, the position is reversed. While it may be eminently desirable that he should have in mind the history of an institution, the important point for his present purpose is the modified form assumed by, say, the chieftainship, or the tenure of property within the family, as a result of the contact of members of the tribe or family group with white civilisation, and the social and economic conditions which have been introduced thereby Still more is it important that he should be able to gauge the course of further development by consideration of analogous conditions elsewhere

Anthropologists in the United States have not been slow to grasp the implications of the changes which are taking place universally in the conditions of life among backward peoples They are now turning their attention to the special methods of inquiry which these conditions demand Dr Margaret Mead, in her book "The Changing Culture of an Indian Tribe" (New York, 1932) has attacked the problem of the outcome of cultural contact on lines which, in part at least, belong to the methods of sociology rather than anthropology Her work, however, points the direction in which a novel technique covering the methods of social studies and cultural anthropology must be developed to meet the special type of problem arising out of the growing industrialism of countries such as India, China and Japan, in which indigenous culture and the conditions of the modern factory worker meet and react

Fortunately for the anthropologist, progress among the majority of peoples of non European culture has not gone so far as to require that he should summon to his aid and adapt to his needs the special methods of sociological investigation in an industrial civilisation The extent, however, to which changing conditions impose a modification of method and outlook upon the investigator who seeks to gauge the tendencies of development where there is a conflict of the two diverse cultures of the so called 'primitive' and civilised worlds, may be estimated from certain recent publications, of which two are by an American investigator and one by a British anthropologist[*] These three publications, though dealing with very diverse and widely separated peoples, nevertheless may legitimately be grouped together in virtue of a certain community of view They mark a change in the orientation of research and, it would seem, open a new chapter in the literature of ethnography

Dr Keesing's valuable study of present-day Samoa and his no less valuable account of his investigations among the hill tribes of Luzon, in which he gives special attention to the achievement of the United States administration, serve to illustrate the application of anthropological method to the diagnosis and treatment of current difficulties His study of Samoa is particularly instructive, for his sketch of native culture as it was before modification by European control shows how far the troubles, which have kept Samoa 'in the news' for so long, were due to a failure to understand the specific character of Samoan social organisation

Dr Mair's study of Uganda stands in a somewhat different category, but her appointment to the recently created lectureship in Colonial administration at the London School of Economics gives it an added interest Forty years ago the Baganda were what it was then fashionable to call 'naked savages', albeit they had a very fairly well-developed culture of their own To-day they dress in European clothes and ride bicycles, but their problem is still to a large extent unsolved How far they have progressed and the direction, may be gauged by Dr Mair's observations on the people and their reactions, and by contrasting them with the record made by the Rev John Roscoe more than thirty years ago

In relation to the more general question, it is perhaps permissible to suggest here that Dr Mair's experience in the field will afford her the basis for developing her academic function in the direction of making her lectureship a link between the more academic side of anthropology and the scientific study of, and formulation of a practical policy in relation to, the changing habits of a people in the throes of a cultural conflict

The present trend of development among peoples of backward culture, therefore, would seem to be leading in anthropological studies in relation to practical affairs to the old and familiar conflict between the 'man in the armchair' and the 'man on the spot', who claims an intimate acquaintance with conditions as they are and, therefore, assumes the sole right to decide upon them Unless the science of anthropology, as understood academically, is prepared to adjust its outlook and to revise its methods to embrace the dynamic as well as the static elements in culture, it is by no means certain that, as in the past, the advantage will be with those who rely on the results of academic training

Art, Science and Morality

Beauty and other Forms of Value By Prof S Alexander Pp x+305 (London Macmillan and Co, Ltd, 1933) 10*s* 6*d* net

IN this work Prof Alexander has applied what Hume called "the experimental method of reasoning" to the investigation of the whole range of values Both the origin and the nature of beauty, truth and goodness are to be understood by considering how human beings came to value them for their own sakes and what human impulses produce them The sciences of value are, as Hume thought they were, sciences of human nature' Their method is psychological and anthropological The differences between the higher or intrinsic values are to be explained as due to the different ways in which a human individual reacts contemplatively' to his natural and social environment, complicated by his instinctive need for conformity with his fellows To account for the opposition between value and dis-value which is found in each of the spheres of art, science and morals, we have to recognise that judgments of value are not purely subjective, but are relative to the 'standard mind' of any given society The measure of the truth of value judgments is neither to be found in any a priori principles apprehended by reason nor in characters which belong to the object valued independently of the evaluator, but in the representative man who embodies the prevailing taste of the society in which he lives Thus in order to account for the existence of standards of value, we do not need to abandon the 'experimental method' or the point of view of human nature Anthropology and sociology will explain, where individual psychology cannot, how standards of value originate, compete and come to prevail

The same method was applied by Prof Alexander to reach very much the same results in "Space, Time and Deity" The most notable feature of the new work is a much more developed and complete exposition of his theory of beauty, which occupies the first half of the book Truth and moral goodness are then briefly elucidated by considering the resemblances and differences between them and the value of fine art, and the 'lower' values of satisfaction in man and the animals are treated finally in relation to, and in contrast with, the 'higher' values

The values of beauty, truth and goodness are not, in Prof Alexander's view, qualities of the objects to which we attribute them He describes them as "relations" between the objects which are called valuable and the evaluator They are "tertiary" or relational qualities which are experienced as the satisfaction by the relevant objects of certain specific impulses in the mind when these have become, as Prof Alexander puts it, "contemplative" Thus beauty consists in the satisfaction of the constructive impulse, truth in the satisfaction of curiosity, moral goodness in the satisfaction of the social impulse In becoming contemplative' these impulses are gratified for their own sake—not in the ordinary course of ordinary practical living—through the creation of a new product (a work of art in the case of beauty an organisation of our passions and desires in the case of moral goodness, a scientific theory in the case of truth), which would not have existed but for the interference of the human mind with Nature These products are created by the corresponding impulses for their own satisfaction, and with them the mind enters into a peculiarly intimate relation which confers value upon them The higher values are thus relative to the mind, but they are not, Prof Alexander insists, subjective, they are objective in the sense that they are relative to a 'standard' or typical mind

Prof Alexander's presentation of his case is intentionally descriptive rather than critical or controversial This has its advantages as well as its disadvantages Throughout the book he is anxious to let the facts speak for themselves and not to twist them in the interests of a metaphysical theory The results of this are particularly valuable in his discussion of beauty, which is happily free from the vagueness and obscurity which are so common in the writings of philosophers on this subject His theory of artistic value, which it is unfortunately impossible to discuss here in detail, is without doubt the most important contribution that any British thinker has made to the study of æsthetics in the present century The same scrupulous respect for fact and sensitiveness to Nature in the concrete which influences his whole treatment is reflected in a singularly vivid and charming style, which is not content merely to describe and analyse, but goes on to present or re-create poetically the facts which he seeks to explain.

It is at the same time doubtful whether Prof Alexander's adoption of a psychological or anthropological method can be justified, and his theory of a 'standard mind' as the basis of our judgments of value made convincing, without a more critical defence of his general point of view than he has given. If the 'standard mind' represents the average level of opinion in any given society about what is true or good or beautiful, it is hard to see what authority it can claim for its verdicts. If, on the other hand, it represents the opinion of the 'expert' in science, art or morals, it must be pointed out that we submit our opinion to the expert's judgment because he knows what really is beautiful or true or good. The expert's judgment is authoritative not because it constitutes the standard but because it conforms to a standard which is 'objective' in the sense that it is independent of human opinions and tastes. Unless our standards of value are objective in this sense, it is hard to see how either progress or retrogression as opposed to mere change, in art, science or morals is possible, or how the question whether the civilisation of one community is or is not superior to that of another which differs from it can have any real significance. If there is any force in these objections, it will follow that the naturalistic method cannot explain what values are, though it may account for their origin and development in relation to the individual or the social group.

Termites and their Control

Termites and Termite Control: a Report to the Termite Investigations Committee. A Discussion of the Biology of Termites, and an Account of the Termites of the United States, Mexico, the Canal Zone, the West Indies, Hawaii and the Philippine Islands, with Recommendations for Prevention and Control of Termite Damage by Methods of Construction and the Use of Chemically Treated and Unpalatable Woods. Editorial Board:—Prof. Charles A. Kofoid (Editor in Chief), Prof. S. F. Light, A. C. Horner, Prof. Merle Randall, Prof. W. B. Herms and Earl E. Bowe. Pp. xxvi+734. (Berkeley, Calif.: University of California Press; London: Cambridge University Press, 1934.) 22*s*. 6*d*. net.

A REPORT of a local committee in San Francisco in 1927 attracted attention to the great damage done by termites in California. The public was alarmed and funds were quickly subscribed by various interests to finance an investigation committee, the report of which has just appeared. It is an elaborate work, the result of the collaboration of thirty-four authors, under a board of six editors. The board of directors of the committee consisted of twenty-four members, operating with thirteen sub-committees.

Although we are exempt from the attention of these insects in Great Britain and only two species are known in Europe, there are no less than fifty-five in the United States, the greater part of which are concentrated in the Pacific coast, thanks to the genial climate and contiguity of the neotropical region. Altogether, about fifteen hundred species are known; twelve hundred of these form the family *Termitidæ*, which are dominant in the tropics, but do little damage. They are rather beneficial to human interests, in spite of their undeservedly bad reputation.

There remain three hundred species divided into four subfamilies which never rest in their function of breaking up cellulose and returning its elements to the atmosphere. Termites are among the few creatures that can digest this refractory material, which they do with the help of an abundant fauna of Protozoa in their intestines.

It is noteworthy that these do not occur in the *Termitidæ* which, living mainly on vegetable detritus, do not require their services. In some genera and even subfamilies, it appears that each species has a characteristic fauna; consequently their Protozoa are a great help in the identification and classification of the termites.

Further, H. Kirby has established the extraordinarily significant fact that similar Protozoa are found in the wood-boring cockroach *Cryptocercus punctulatus* and that in the cockroaches the flagellate genus *Trichonympha*, which is widely distributed among the termites, is represented by several species. This is striking evidence in favour of the accepted view that the termites branched off from the ancestral cockroach towards the end of the Palæozoic era.

Their natural function as destroyers of cellulose brings termites into antagonism with man. It is estimated that the damage done by termites in the United States amounts to no less than 37,000,000 dollars per annum, three quarters of which is in the southern and western area. All wooden structures are mercilessly attacked—power transmission, telegraph and telephone poles, timber stacks, wooden buildings, and interior wooden structures, even furniture.

The use of steel for telegraph poles and railway sleepers, and increased use of cement in building, have reduced termite damage substantially in the tropical parts of the British Empire, but the actual and potential importance of the creature is so great, and so little investigation has been conducted into the problem, that this important work should be welcome to architects, surveyors, engineers, indeed by all users of wood in the tropics, where it is estimated that termites add 10 per cent to the general cost of construction

The two methods of attack are construction and treatment Owing to the diversity of habits of the creature, the first need is to study the local termites and adapt methods accordingly As an example of construction may be mentioned the raising of woodwork above the ground so as to eliminate moisture and prevent attack by those species which do not make runways

A long series of laboratory experiments has shown that treated wood is proof only if rendered toxic The most satisfactory results were obtained with copper sulphate, sodium chloride and zinc chloride Paint is only a deterrent, fumigation and ground treatments are unsatisfactory, the best results against dry wood termites were obtained by the use of poison dust as Paris green arsenical smelter dust and finely ground sodium fluosilicate The extract of American redwoods, sequoyin and isosequein two newly discovered substances with remarkable properties, were found to be highly toxic to termites

Architects will find great interest in the last chapter with recommendations for construction, for inspection and maintenance, for preventing and repairing damage It is to be noted that the engineer must often rob Peter to pay Paul, as construction and maintenance may be in conflict

Conditions are so varied that no golden key can be found, but it seems that the impregnation of wood with coal tar creosote by pressure treatment gives the most lasting and satisfactory results under severe conditions As wood frame construction has been recommended as the best design for resistance to earthquakes, it is especially necessary to take adequate action against these pests in regions so liable

The work is placed upon the market at a minimum price, and results of sales will be applied for the benefit of further research The biological portion is of very great interest to entomologists and is a notable addition to the literature of the subject, but the practical portion, on which the existing literature was quite inadequate, is of great value to all architects, engineers and users of wood engaged in construction in all tropical, and many subtropical, countries, and consequently of definite moment to officials and settlers in our African, Oriental and Australian dominions and territories

Industrial Organisation

The Logic of Industrial Organization By Dr P Sargant Florence Pp xi+280 (London Kegan Paul and Co Ltd, 1933) 10s 6d net

FROM the author of such a work as the Statistical Method in Economics" previously reviewed in these columns, one confidently looks for a clear and orderly presentation of the relevant facts and logical deduction therefrom and in this latest book by Prof Florence one is not disappointed His main purpose is an examination of the structure and functioning of modern industry to show how this structure and its working are for the most part anything but logical or even properly organised, and to suggest methods for remedying this serious defect

At first sight one might suppose that the ideal of organised industry is that of a perfectly designed and constructed machine which, despite its almost infinite complexity, functions with the cold precision of a highly efficient machine on a thoroughly logical production schedule One might suppose further that, if this ideal be completely realised then the mechanisation of industry of which we hear so much would indeed be advanced to a terrible and ruthless stage, both literally and metaphorically not only would industry throughout its entire length and breadth use the most efficient mechanical means available in all its operations but industry itself would also be closely akin to a huge complicated yet perfectly designed mechanism, and the evils of modern industry would be intensified a hundred fold If, for example, we already get over-production and under employment owing to the increased efficiency and output of machines, to what almost inconceivable extent would this strangely combined excess of one and defect of the other be carried if industrial organisation itself could be likened to a giant machine of maximum efficiency ! Of course if this ideal could be properly realised it might mean the total elimination of unemployment in some mysterious way that we cannot foresee, but this is most unlikely However, such realisation is a very long way off, as this work clearly shows, and in any event this conception of industry as a huge soulless machine is certainly not that of the author

Most emphatically no, for the human or psychological factors of modern industrialism are here given full weight and first consideration The worker is not to be sacrificed to mere output, even if he were a willing victim of such immolation, and the enlightened employer realises more and more clearly that, even from the point of view of maximum production if not from the higher humane and moral point of view, the workers must be treated as men and fellow creatures as members of one great brotherhood. If he does not realise it, then the workers very soon make their point of view clear to him and refuse to be exploited. In the present book one of the most valuable and interesting chapters is that dealing with labour stimulus and incentives in which special emphasis is laid on those fundamental characteristics of human nature which so largely determine a man's attitude to his work and his reactions to the conditions of employment.

The aim kept in view throughout the book is that of industrial efficiency defined as maximum return—physical, pecuniary and psychological—at minimum physical, pecuniary and psychological cost, and a fairly thorough study is made in general terms of modern industry in Great Britain, with frequent references to Germany and the United States. A rapid survey of the whole subject matter may be readily obtained from the 'Conclusions' concisely stated in chap. ix, and one can readily see from a good index that among the many vital topics dealt with, administration and training for same, capital and investment, directors and their methods good and bad, labour and work conditions, transport, and so on, are fully treated.

The part played by education and training in industry is to-day of particular importance and the author's criticism of English education from this point of view, though severe, will scarcely be deemed too drastic. He thinks that our educational system requires radical alteration if it is to help in supplying efficient industrial administrators. On the subject of unemployment the chief suggestion appears to be a more logical distribution of work, mainly by shorter hours, but this bald statement scarcely does justice to the author's contribution to this burning question of the hour. Chap. iv, dealing with investment, employment, management, deserves close and careful reading. Indeed, this applies to practically the whole work, for it sticks closely to the facts of our everyday working life, wastes few words on theorising or philosophical speculations, is nothing if not logical, and is for the most part in the straightforward indicative mood, though the optative—as with any humane writer however factual or statistical—must obtrude now and then.

Plant Analysis

Handbuch der Pflanzenanalyse. Herausgegeben von G. Klein. Band 4: *Spezielle Analyse.* Teil 3: *Organische Stoffe III. Besondere Methoden, Tabellen.* Hälfte 1. Pp. xii+838. Hälfte 2. Pp. vi+839–1868. (Wien und Berlin: Julius Springer, 1933.) 198 gold marks.

THE two volumes now under notice complete this comprehensive work which has already been noticed in NATURE (130, 617, Oct. 22, 1932; 131, 8, Jan. 7; 132, 584, 1933). They deal, in the first volume, with the amino acids, amides, amines and the betaines, all written by Dr. A. Winterstein, the proteins compiled by Bergmann and Zervas, nucleins by Steudel and Peiser, alkaloids by Seka, cerebrosides by Thierfelder supplemented after his decease by Klenk, all being authorities of repute. In the second volume, Dr. Sjöberg discusses enzymes in general whilst Dr. Ziese deals with them in detail. The plant antigens are described by Eisler, the plant hormones by Loewe, plant vitamins by Winterstein.

A final section deals at length with special methods of biological analysis, soil analysis; it has a chapter descriptive of the various fermentation processes by Kobel and Neuberg, another handling the nitrogen balance and a very valuable section on plant pigment analysis by chromotographic adsorption methods by Winterstein.

The work concludes with more than 300 pages of tables and index in which all the known plant constituents are listed in alphabetical order with their formulæ, physical constants and solubility.

The above details indicate merely the wide scope of the work, so that it is necessary to testify also to the thoroughness and completeness with which the respective subjects are put on record.

Since our previous review was written, we and several of our younger colleagues have had opportunity to make frequent reference to the earlier volumes which have proved to be of the greatest use; it is only fair therefore to accord to Dr. G. Klein, the editor in chief of the monumental work, the appreciation of those who are working in the field of plant chemistry. It is one which for some time past has been largely neglected, in part owing to the superior attraction offered by problems in animal chemistry, especially the vitamins; but there are signs of a change in fashion, and the problems of the plant are now attracting the attention of many of the younger workers. To them such a summary at the present time is of importance not only for the information it contains, but also because it is definitely stimulating in indicating the loopholes and the possibilities for new work

A word of praise must be given also to the publishers for their enterprise, even if tempered with some expression of regret at the price which is charged Expressed in our currency, the cost puts the ownership of the book outside the reach of all but the most wealthy library, whereas it ought to be widely available for reference purposes

It is obviously out of the question to attempt any detailed analysis, rather must the book be viewed as a whole, as a record of the present state of knowledge of plant products discovered by the organic chemist Very nearly all the substances have yielded to his artifices, many only during the last decade, in spite of their complexity, fats, sugars including starch and cellulose, the proteins, alkaloids, saponins, nucleic acids, the plant colours, all have their secrets laid bare—only a few details as to their configuration are withheld The attack is now on the most complicated constituents of the cell, on the ferments, the hormones and the more complex proteins Here and there may be found isolated compounds to be investigated among the glycosides, the arrow poisons or elsewhere, but the time has come to establish group relationships, to correlate structure with physiological activity, to seek the origins and the function of compounds of such complexity in plant life

Had the achievement been a literary one, there would have been the excuse to rhapsodise over its greatness, to bestow laurel crowns, but in science it is otherwise—we are accustomed to pass quickly from the problem solved to the many more which await us, each new worker taking up the torch from the fallen, content to add his mite to the general store of advancing knowledge

E F A

Short Reviews

Weather the Nature of Weather Changes from Day to Day By the Hon Ralph Abercromby New edition, revised and largely rewritten, by A H R Goldie Pp xii+274+8 plates (London Kegan Paul and Co, Ltd, 1934) 10*s* 6*d* net

THE original edition of this work by the Hon Ralph Abercromby appeared in 1887 and attracted much attention, passing through seven editions without change Abercromby set out very effectively the principles of synoptic meteorology, and his generalisations and ideas have become classical The early hopes of forecasting weather from the travel of cyclones and maps of limited area were not, however, realised, and it is now accepted that 'the whole world is the meteorologist's laboratory' In the new edition, Mr Goldie has developed the physical principles and included present-day knowledge of the upper air and modern theories A recent weather chart of the northern hemisphere shows the enormous advance which has been made in organising observations

The book is fully illustrated and includes some fine cloud photographs, and these are discussed in relation to the synoptic charts Bibliographies are given which cover matters that could not be treated completely in the text Many interesting examples of weather are described in detail with the help of charts and diagrams The style is clear and will appeal to the general reader as well as the student Almost every aspect of the subject is discussed, including the Bergen theory of cyclones, the relation of wind to pressure distribution, line-squalls and thunderstorms, visibility and fog, tornadoes and the general circulation—all matters of great practical importance

АТОМНОЕ ЯДРО (*The Atomic Nucleus*) Edited by M P Bronstein, W M Dukelski, D D. Iwanenko and U W Khariton (Problems of Modern Physics, No 24) Pp 227 (Leningrad and Moscow Izdatel'stvo, 1934) 3 rub

THIS book (in Russian) consists in the main part of the description of papers, which were contributed to the First All Russia Atomic Nucleus Congress held in Leningrad on September 24–30, 1933, together with some of the discussions that followed Eleven papers are included

The contents start with a paper by F Joliot on neutrons, which is a summary of present-day knowledge of neutrons, description of the methods of production and conditions of their emission, and finally a discussion of their possible mass Then follow two rather theoretical papers by F. Perrin and D. Iwanenko on the constitutive parts or units in atomic nuclei After a paper by D Skobeltzyn on the problems of cosmic rays, positron theory is discussed in two papers by P A M Dirac and F Joliot

Methods used for obtaining high speed electrons and ions are described by K. Sinelnikow, particularly the methods in use at the Ukraine Physico-Technical Institute in Kharkov, where an impulse generator of 1 5 millions volts produced electrons fairly readily with the speed of 1 3 million volts

There are also papers by L Gray, S Frisch and F Rasetti

The last paper, by A Leipunski, deals with the breaking down of atoms and gives a summary of recent work done by Lord Rutherford and co-workers

Coast Erosion and Protection By the late Prof E R Matthews Third edition revised, with an additional chapter and an appendix, by Dr Brysson Cunningham Pp xviii+228+36 plates (London Charles Griffin and Co, Ltd, 1934) 12s 6d net

THIS work, which is the third edition of the late Prof Matthews's book on coast erosion and protection, consists very largely of a record of the long experience of the author in dealing with these problems It deals with the erosion and accretion that is taking place around the coasts of Great Britain and with the various types of sea defences, the merits and defects of each type being discussed in detail There is some discussion of the action of sea water on concrete, while the effect of harbour projections on the travel of sand and shingle is briefly referred to The present edition also contains a chapter on recent practice by Dr Brysson Cunningham, and an appendix giving the conclusions on coast protection drawn up for the International Association of Navigation Engineers in 1931

The book is based mainly on papers read by Prof Matthews before various learned societies and articles contributed by him to technical journals at different times These have been collated and are presented in a somewhat disjointed form The illustrations are lavish There are many useful detailed sketches of existing sea walls, groynes and breakwaters and a very large number of photographs, excellent in their way but of no particular technical value, illustrating the breaking of waves on sea walls and breakwaters, cases of cliff erosion, and the like As a record of the personal experience of Prof Matthews, the book should be of use to the engineer engaged in similar work

Biologie der Tiere Deutschlands Herausgegeben von Prof Dr Paul Schulze Lieferung 36 Teil 26, *Orthopteroidea* I Von Max Beier Pp 231 (Berlin Gebrüder Borntraeger, 1933) 16 gold marks

THE present part of this work contains three chapters respectively on the Blattoids (cockroaches), the Dermaptera (earwigs), both by M Beier, and on the Mantids (praying insects) by M Beier and J Jaus The longest of these is the first (116 pp) which forms an admirable account of the external features, internal anatomy, life-history and physiology of the cockroach, based chiefly on *Phyllodromia germanica* Particular attention is given to the structure and physiology of the nervous system and the alimentary tract The account forms an excellent source of reference for information, brought well up to date, on this much used laboratory type

The description of the earwig (63 pp) based chiefly on *Forficula auricularia*, which will also be useful to British students, follows similar lines with the addition of a short section on the chromosome numbers—$22+2x$ in female and $22+xy$ in the male and on the variation in size in the cerci

The chapter on the Mantids, largely on *Mantis religiosa*, directs attention to several special features of interest, for example, the pigment change in the compound eyes in the evening, the chromosome constitution of male and female, neoteny and regeneration

The illustrations of all the chapters are well chosen and admirably reproduced, and to each chapter a useful bibliography is appended

The Statesman's Year Book Statistical and Historical Annual of the States of the World for the Year 1934 Edited by Dr M Epstein Seventy first Annual Publication Revised after Official Returns Pp xxxiv+1478 (London Macmillan and Co Ltd 1934) 20s net

AGAIN this invaluable work of reference provides not merely a statistical guide to the countries of the world, their area, population, production, trade and finance, but also an epitome of almost every aspect of public life The arrangement follows the usual plan the British Empire with nearly a third of the book followed by the United States dealt with as a whole and then by each State in turn, and finally other countries arranged alphabetically with the overseas possessions belonging to each All the figures have been revised by the latest returns available A year that has seen turmoil in several States has not witnessed any material changes of boundary The adjustment between Iraq and Syria is shown on one of the two maps the other of which illustrates the progress of French civil administration into the interior of Morocco during recent years The introductory tables, which might well be increased in number if space allowed, give the world's production of petroleum, iron and steel, cocoa gold and cotton and the world's fleets and mercantile marines There is a summary of the work of the League of Nations

The Kinetics of Reactions in Solution By Dr E A Moelwyn Hughes Pp vii+313 (Oxford Clarendon Press, London Oxford University Press, 1933) 15s net

A GENERATION back the application of the kinetic theory to chemistry was restricted to the reactions which occur in gases Progress has enabled reactions in solutions to be examined in the light of the same theory with satisfactory results The author has selected certain representative examples for his purpose and has produced a treatise which will undoubtedly be of value to the advanced student and worker in physical chemistry The scope is best illustrated by the table of contents, the respective chapters deal with the collision theory, the Arrhenius equation, a comparison of the kinetics of reactions in the gaseous phase and in solution, and then pass on to bimolecular and unimolecular reactions, equilibria, ionic, catalysed and heterogeneous reactions

Fifty Years Ago, in the Royal Society of Edinburgh[*]

By Prof. D'Arcy Wentworth Thompson, C.B., F.R.S.

THE Royal Society of Edinburgh was a hundred years old just fifty years ago. We are looking back across those fifty years as on a remembered road whereon we all have travelled. Let us step across Princes Street and pay a visit to the former habitation of the Society.

We pass through a vestibule and enter those beautiful apartments, one opening into another, at which some of us still glance enviously through the tall pillared windows at the foot of the Mound. In the first room surrounded by books at a table which we use still an old man sat reading all day long. It was said of him that few men had absorbed more learning and exuded less! He was the Society's librarian Mr. James Gordon. He wore a long, wide skirted frock coat and a black satin stock came close up to his clean shaven chin. He had a shy but dignified manner and a hesitation almost a stammer, in his speech. He wrote the easy, fluent sonorous Latin of the cosmopolitan scholar and loved to write addresses to be sent abroad to some university or academy. He wrote such a one when Wyville Thomson went to Uppsala for the Linnean Centenary in 1878, and I remember hearing Wyville tell how much it had been admired by the Swedes. So we looked for it the other day and found it in our minutes: *Amplissimis Curatoribus, Rectori Magnifico, Doctissimoque Senatui Universitatis Upsaliensis* — and so on!

In the next room, a long and beautiful room, our meetings were held. Five large windows looked out on the Castle and the Gardens; but the meetings were at eight o'clock, and the curtains were drawn. Opposite the windows the bookcases were kept low, and there the portraits hung:—our Walter Scott, and Sir James D. Forbes, and Sir David Brewster, and Sir T. Makdougall-Brisbane, and Raeburn's portrait of old John Robison, and later on George Reid's portraits of Christison and of Tait. Half way up the room, on the window-side, was the president's chair, raised a little, and the table where (as now) the secretaries and other officers sat. On the far side, looking down the room towards the entrance, Tait sat for nearly forty years. I think of Crum Brown, wearing his little velvet cap, sitting beside Tait; of Buchan, at the opposite corner, stroking now and then his long red-brown beard; and Kelvin's eager restless figure in the chair.

Let us recall a certain older meeting, of not fifty but sixty years ago, sixty years almost to a day. David Milne Home was in the chair, and papers of the usual kind were being read. George Forbes (to-day the oldest of our fellows, save one), son of Tait's illustrious predecessor, talked of an optical illusion which Tait had noticed one sleepless night. Edward Sang had something to say on the properties of fluid drops within crystal cavities; and then a paper was read by a young author, rather a dull paper, on the "Thermal Influence of Forests". It dealt with the island of Malta, where the chairman had a scheme for the planting of trees. It made a good show of meteorological learning, quoting Réaumur, Humboldt, Becquerel, Boussingault, and Scoresby Jackson's "Medical Climatology". Its style was technical and scientific rather than literary:—"In addition to the ordinary hours of observation special readings of the thermometer should be made as often as possible at a change of wind, in order to admit of the recognition and extension of Herr Rivoli's comparison" —and so on. It was almost the first thing the author ever published, and the only scientific thing he ever wrote. He did better, much better, later on, when he wrote a book called 'Treasure Island'!

Two events influenced our Society and the scientific world of Edinburgh fifty and sixty years ago. One was the return of the *Challenger* Expedition; the other was the publication of the famous ninth edition of the "Britannica". Just as Robison and Playfair and Brewster and Dugald Stewart, and other members of our young Society, had been contributors to earlier editions, so fifty and sixty years ago, under Baynes and Robertson Smith, scientific Edinburgh was kept busy writing articles, and who should do this and who should get that was discussed eagerly. I can remember a little outburst of Tait's when "Astronomy" went to a certain popular writer whom Tait held to be outside the pale! But soon afterwards, Clerk Maxwell drew up a scheme for the chief scientific articles, and began by writing the article "Atom", in which Kelvin's vortex atoms, by the way, had full justice done them; and then he wrote his beautiful article "Capillarity"; and Tait wrote on "Light" and on "Mechanics", and Chrystal wrote famous articles on "Electricity" and "Magnetism"; and Crum Brown wrote a most original article on "Molecule". Besides these and such as these, there were endless biographical articles: Tait's on Sir Wm. Rowan Hamilton among the chief, and Chrystal's on Pascal, Poisson, Riemann and many more. It was a busy time when all these were being written.

As the Encyclopaedia brought the learning of Great Britain to an Edinburgh printing house, so did the *Challenger* Expedition make Edinburgh a centre for the naturalists of the world. Wyville Thomson was a weary man and out of health when he came home from the sea, and he died before his work was done. John Murray, the strong, able man who took his place and filled it bravely, has overshadowed Wyville's name and memory, but we few who knew him hold him in honour and affection. He had begun as a boy-naturalist by the East Lothian shore, as did old Sir John Graham Dalyell and Francis Maitland Balfour and many and many another. He came under the potent influence of Edward Forbes, who, with Goodsir, was the first to borrow the oysterman's dredge and begin the endless task of the exploration of the sea. With Carpenter, Wyville explored our western waters in the *Porcupine*, and made the cardinal discovery of the warm and cold waters of the Faeroe Channel, on either side of the submarine ridge which bears his name. We owe to him the grandiose conception, the splendid programme and the immense achievement of the *Challenger* Expedition, and the planning on a noble scale of the publication of its results. He saw before he died a few parts of the great publication.

---

[*] Part of an address delivered in Edinburgh on Monday, May 7, 1934, on the occasion of the Society's hundred and fiftieth anniversary.

Wyville Thomson was a kindly man and faithful to his friends. He would search all Europe and America too to find the best man to deal with this group of animals or that, but if he found no such specialist he would pick out some friendly naturalist at home or some young pupil of his own. So he gave a certain large group to a very young student, my school fellow Willie (afterwards Sir William) Herdman; and Herdman brought his first reports before this Society and became in time the chief authority on the Tunicates in the world.

Herdman was a schoolboy at the Edinburgh Academy sixty years ago, and three other boys, sitting in the same small class, all became fellows of this Society, to one of these four, Dr. J. S. Haldane, we are to-day paying the highest compliment in our power! Some five and twenty years before, other four boys were at the Academy together, all fellows of our Society in after years—Tait and Fleeming Jenkin and Lewis Campbell, and Clerk Maxwell, who towers over all. Maxwell paid our Society his first visit when he was twelve years old. At fifteen he wrote his first paper for us, on "The Properties of certain Oval Curves", and when he was sixteen, a student under J. D. Forbes, he wrote another, on "Rolling Curves or Roulettes". But Forbes had to read both of these papers, for it was not thought proper for a boy in a round jacket to address the Society! We have just had the rare luck to discover the MS. of the former paper, in Maxwell's schoolboy hand, together with Forbes's report or epitome, which latter, and not the paper itself, was published, in 1846, in our *Proceedings*.

Let us think of a few more who were men of mark here fifty years ago. As to Lord Kelvin, I can add nothing to what has been so often said, of one who is so well remembered. He was a fellow of the Society for sixty years. His papers on the theory of heat, on hydrodynamical questions, on vortex atoms, on gyrostats, on close-packing of atoms and what not more, adorned our *Transactions* for a long generation. He was the unquestioned leader of the Society, the master of all. He was president until his death, except for the few years when that office was incompatible with his presidency of the Royal Society of London.

Alexander Buchan sat at the table for years as treasurer, a tall and striking figure. He was a humorous man, and showed it by the twinkle in his eye. He said once: 'Everybody thinks me taller than I am; and wiser than I am, and better than I am"—this last having something to do with the fact that he was an elder under Dr. Whyte in Free St. George's! The 'spells' which have made his name a household word have little to do with his real fame. Seventy years ago he had mapped the isobars and isotherms of the world and laid the foundations of all we know of atmospheric circulation. He was probably the very first to show that 'weather travels'; on which cardinal fact all our weather forecasting depends.

Fifty years ago Prof. Turner (not yet Sir William) was one of the secretaries to our ordinary meetings, and in 1908, when Kelvin died, he became by acclamation president of the Society. There is scarcely anyone of whom I have so old a memory, for I remember one day, in the year 1867, an uncle of mine rushing into our house, waving his arms, and crying "Turner's got it"! I told Turner so fifty years after in the Athenæum. He was extraordinarily delighted, he laughed and chuckled, he made me say it all over again. For that had been the great day of his life, when he was elected to Goodsir's chair, after a hard fight with Struthers—to the boundless delight of all the younger men.

Turner lived so long that we can all remember him: his sturdy figure, his rapid walk, his little shake of the head, the twinkle of his eye, his dominant personality. He was a trifle pompous sometimes and fond of the verbiage of the anatomists. He came along when I was doing my first day's work in the old dissecting room. 'Well, what have you got?" said he. "An arm, sir,' said I very timidly. 'Call it a superior extremity, it's so much more precise!' As a demonstrator he was superb. One did not forget one's lesson in a hurry, when Turner had held up nerve or artery in his forceps, and told their names with such a look and voice as though the world depended on them. Of the papers which he read before our Society, many were about whales, for he inherited a lifelong interest in these great beasts from Knox and Goodsir. Turner had none of the poetry, imagination or insight of Goodsir. But there was nothing Turner touched that he did not do with all his might, his love of his subject, his faith and enthusiasm, never flagged for a moment. He was a teacher and a master of men. He fairly won and manifestly deserved the honours that were heaped upon him.

Fifty years and one more year ago, Benjamin Peach was put in charge of the geological survey of the North-West Highlands. Then began a famous chapter in the history of geology, and the unravelling of one of the most difficult regions in the world. It was Peach who first showed the unconformity between the Cambrian rocks and the still older strata; he studied the stupendous thrusts of the great rock masses of the north-west; and he delighted in the old Cambrian fossils of Durness, which his father, coastguardsman at Wick, had been the first to discover. I do not know that Charles Peach, the father, was ever a member of this Society; but I will not let his name, nor his son's name, pass, without paying something of the debt he laid me under. He was a famous naturalist of the old simple school. I and two or three others came under his spell when he was very old and we were boys; and what he taught us, and the love of living things he shared with us, has been worth much to me. What he taught his son was a great deal more. It made him one of the keenest observers, one of the greatest palæontologists and geologists of his time. Both father and son were men of unusual strength and immense vitality; their voices and their laughter come ringing down the years!

Dr Edward Sang, teacher of mathematics, died some forty years ago; he had been a candidate for the natural philosophy chair when Tait won it over Clerk Maxwell. Fifty years ago, an old man Sang was busy constructing his wonderful tables of logarithms, which have never been printed but are among the Society's most prized possessions. They were among the first tables to be independently calculated since Briggs and Vlacq made theirs, immediately after the "Canon Mirificus". All but a hundred years ago, Sang had read a paper to our Society on Nicol's polarising prism—Nicol being an Edinburgh optician who had just invented this indispensable instrument. Sang's paper was never published, no one knows why; and when he was dying he spoke of it to Tait, and said he thought he had never written a better thing. Tait made instant search for the paper, had it read and printed, but poor Sang was dead. Had it been published when it was written it would have been one of the important scientific papers of the time; it contained things which were not said again for nearly fifty years.

John Aitken of Falkirk also lived to a great age, and was a notable figure of our Society fifty years ago. The greatest of all discoverers are those who discover the simplest things, and John Aitken was one of these. 'Why is one's breath visible on a frosty day?' was a question asked, by James Hutton, in one of the first papers ever read before this Society; and Aitken answered it, a hundred years later, in his papers on dust and fog and cloud. How fog and cloud, and all the colours of the sunset, are due to dust particles in the air, dust far smaller than the motes in a sunbeam; how and why the colours of the sunset were intensified fifty years ago, after the eruption of Krakatoa; how and why and when the 'New Moon holds the Old Moon in her arms'—these are some of the things that John Aitken has explained.

George Chrystal came to Edinburgh five and fifty years ago, welcomed with exuberant delight by Tait and others. He was physicist as well as mathematician. He had been one of the first pupils in the Cavendish Laboratory, where Maxwell set him to work on Ohm's law. When he had done, Maxwell said that seldom or never had so searching a test been applied to an empirical law; and he added the curious remark that the way it had stood the test encouraged one to believe that the very simplicity of a physical law might be taken as some indication of its exactness! In later years Chrystal became interested in the oscillations or solitary waves on certain lakes, to which, in Switzerland, Forel had given the name of seiches. Here he found simple experiment and difficult mathematics after his own heart; and the work which he and a certain younger member of this Society did on seiches is as beautiful and as complete an investigation as was ever brought before our Society.

When Chrystal went to Cambridge he found it (as he afterwards said) 'almost decadent as an educational institution"; while in Cayley, Stokes, Adams, Maxwell, it had perhaps the greatest galaxy of talent in all its history! Chrystal became an enthusiast for education, striving to do here what the Cavendish Laboratory was doing and has done in Cambridge; giving mathematics a meaning, direction and purpose, of which the coach and the examiner had not dreamed. I was in our College Library a day or two ago, and two lads were reading diligently near by. I had the curiosity to look at the books they left behind, and both had been reading Chrystal's 'Algebra'. I opened the book at a random page; the chapter was on certain transformations of circular functions; but the interesting thing was to see how Chrystal guided the student, in a few lines, to Riemann on one hand and Cayley on the other; and then to Maxwell and his lines of force and equipotential, and so to an endless variety of physical problems. Between such algebra, a weapon in the hand of the physicist, and the algebra of the old school books, there is all the difference in the world.

With a certain peculiar affection we look back upon Crum Brown. He was one of our secretaries for a quarter of a century and a member of Council for more than forty years. I have already spoken of him sitting quietly at the table, with his little velvet cap upon his head, keenly alive to everything but speaking seldom. Once indeed he brought down the house, with a sort of magic bottle, which squeaked out vowel sounds in a voice not unlike his own, and in so doing demolished a theory of Fleeming Jenkin's to which the Society had listened a few nights before. We students behaved none too well during his lectures, from which we came across the quadrangle to sit quiet as mice under Tait. But we learned afterwards how fine, how erudite, how prescient, how suggestive, how educative Crum Brown's lectures had been.

He was a man of very great originality, he was always before his time When he took his degree, at three-and-twenty, his thesis "On the Theory of Chemical Combination" won no prize, nor was it printed until many years afterwards, but it was a wonderful exposition of structural chemistry, and contained a system of graphic formulæ, undreamed of at the time, but to all intents and purposes that which came ultimately into universal use He began teaching in a little extra-mural laboratory of his own in High School Yards, to the smallest of classes He used to come down to our house of an evening and say (in a voice that some of us can still hear) "As I was saying to my man to day!'—this was his only student The great John Hunter himself had once no more! But when the University chair became vacant on Lyon Playfair's retirement, Crum Brown was known to and recommended by Bunsen, Hofmann, Wöhler, Baeyer, Kolbe, Beilstein—in short, by the greatest chemists of the day

He was a man of insatiable curiosity, interested in what he did not know more than in what he knew He wrote an important paper on the semicircular canals of the ear and their functions and illustrated it by curious experiments and exquisite anatomical preparations He had a passion for making models, geometrical and other There were times when the glue pot was always by his fire, and cardboard always ready to his hand, when he was very old indeed he lay quietly knitting, and the little mats he knitted were recondite models of interlaced figures and interwoven surfaces He had both of these hobbies in common with Maxwell For Maxwell had made some of the same models when he was a schoolboy, and his are in the Cavendish Laboratory to this day, and he once knitted a kettle-holder gayer than the rainbow, for it depicted a square of unannealed glass placed between crossed Nicol's prisms

Crum Brown was at heart a mathematician. He said that unless the young chemist learns "the imperial language of science", the higher branches of chemistry (which require reason as well as skill) will pass out of his hands

I sat in Tait's classroom for the first time well-nigh sixty years ago; and I remember as if it were yesterday the opening lecture which he gave It was on the rainbow and the aurora—and the moral of it was to show how, of two phenomena, one may have been brought within the knowledge and comprehension of mankind, while the other, no less common nor less beautiful, remains a mysterious pageant beyond our ken The days went by and every morning Tait gave us of his best, and all he taught us seemed to be just what we had most wanted to know We also learned the very important lesson (as Prof Flint long afterwards said) that here was a man whose mind was immeasurably greater than our own

Tait played with schoolboy zest when it was playtime, and turned easily from work to play Kelvin said of him that he had made the writing of "T and T' " a perpetual joke, his papers here on "Knots" were one long game—always with the joke behind it that in four dimensions there would be no knots at all! Even in class, once in a way, when he had drawn a freehand circle on the board or skilfully thrown a skipping rope into waves, his eye would meet ours in momentary triumph and schoolboy comradeship But in fact Tait's life was one of arduous and almost continuous labour, play there might be, but idleness never, and with duty nothing was ever suffered to interfere Until the end grew near, when his natural strength abated and sorrow came at the last, he kept the light heart and the happy laughter of a boy, and we who were his pupils, forty, fifty and sixty years ago, still think of him with love, honour and gratitude, and know by a lifetime's experience how rare and exceptional were his qualities of heart and mind

---

Muhammad Ibn Umail: an Early Muslim Alchemist

NEARLY twelve years ago, it was mentioned in NATURE of October 28, 1922, p 574 that a well known Latin alchemical treatise entitled "Epistola Solis ad Lunam Crescentem" was apparently a translation of the Arabic work "Risālatu'l-shams ilā al-hilāl (Letter of the Sun to the New Moon) by Muhammad ibn Umail al-Tamimi. This suggestion has been confirmed by Messrs Muhammad Turab Ali, H E Stapleton and M. Hidayat Husain, who, in a lengthy and valuable communication to the *Memoirs of the Asiatic Society of Bengal* (vol 12, No 1, pp 1–213; 1933), have published the Arabic text of (*a*) the Risāla, (*b*) a prose commentary on the Risāla, by the author himself, entitled "Al-mā' al-waraqī wa'l-ard an-najmīyah" (Book of the Silvery Water and Starry Earth), and (*c*) a further poem of Ibn Umail's, entitled "Al-qasidat an-nūnīyah" (Poem rhyming in Nūn) The edition of the texts is the work of Mr M Turab Ali, Messrs Stapleton and Hidayat Husain contribute an excursus on the date, writings and place in alchemical history of Ibn Umail, an edition, with glossary, of an early medieval Latin rendering of the first half of the Mā' al-waraqī, and a descriptive index, chiefly of the alchemical authorities quoted by Ibn Umail

Ibn Umail was formerly believed to have flourished in the second half of the third century A H (that is, A D 864–912), but it is now shown that this date is too early Upon evidence deduced from the period at which his friends, and authors he makes use of, are known to have lived, it appears that his life probably covered the years from 900 to at least 960 A.D, and that his writings are consequently later than those of Razi (Rhazes)

The statement of the bibliographer Ḥājjī Khalifa that his name was not pronounced Amyal (as has sometimes been supposed), but Umail, is confirmed by the vowel points placed on the name in the Leningrad manuscript of the work. It might, however, be mentioned in this connexion that Ḥājjī Abdu'l Muhyī, who possesses a very extensive acquaintance with Arabic alchemical literature, and whom the present writer consulted on the point a few years ago, was emphatically of opinion that the correct pronunciation was Amyal. The Latin transcription Hamuel would support the latter as against Umail; it is therefore difficult to arrive at a final decision.

The importance of Ibn Umail's work lies in its early date, in its possible affiliations with the celebrated "Turba philosophorum", the 'Shawāhid" of Razi, and a treatise by the little known alchemist Mahraris, and in its richly detailed picture of Muslim alchemical thought of the tenth century. Messrs Stapleton and Husain promise us a detailed study of the text of the Mā' al waraqī and its comparison with the work of Razi just mentioned, as soon as leisure from their official duties permits. Meanwhile, an inspection of the Arabic version side by side with the Latin translation shows that while the latter is a creditable production for its age, the translator made a great many slips and not seldom failed completely to understand his author. Those historians who can read Ibn Umail in the original will find an abundant store of important and interesting information in Mr Turab Ali's carefully edited text, but the general reader of alchemical literature must impatiently await an annotated English translation and hope that Mr Stapleton may not long delay it.

The descriptive index of names of people, countries, places and books mentioned in the Mā' al waraqī, with its Latin rendering, and in the Qasīdat an nūnīyah, is largely the work of Prof. Maqbul Ahmad, of Presidency College, Calcutta. It is by no means the least valuable part of the treatise, for it throws considerable light on those personages, real or fictitious, then regarded as authorities, and shows at a glance the books most frequently quoted and therefore presumably esteemed most highly. We note, for example, that Jābir ibn Hayyān is mentioned 31 times, Mary the Jewess 27 times and Hermes no fewer than 51 times. But we feel that we should like to know more of Abu'l Qāsim 'Abdu'l-Mahmūd ibn Ḥayyān, an unsuccessful alchemist and contemporary of Ibn Umail, who worked for twenty three years without letting his furnace go out!

E. J. HOLMYARD

Obituary

PROF. E. W. HOBSON, F.R.S.

ERNEST WILLIAM HOBSON, who was born at Derby on October 27, 1856 and died rather suddenly, after a short illness, on April 19, 1933, had been for many years one of the first of English mathematicians. Although he lived to be seventy six, he was active almost up to his death; his last book (and perhaps in some ways his best) was published when he was seventy four. He was a singular exception to the general rule that good mathematicians do their best work when they are young.

Hobson was the son of William Hobson, who was editor and part proprietor of the *Derbyshire Advertiser*, and was prominent in municipal affairs. He was the eldest of a family of six, J. A. Hobson, the well-known economist, being one of his brothers. His early education was at Derby School, where his mathematical talents were very soon noticed and encouraged. When he was fifteen he obtained a Whitworth Scholarship at what is now the Royal College of Science, and studied physics in London for a short time under Dr. F. G. Guthrie. Two years later he was elected a mathematical scholar of Christ's College, Cambridge. He went into residence in October 1874, 'coached' with Routh, and was Senior Wrangler in 1878.

A S[illegible]r Wrangler of those days succeeded almost [illegible] of right to a fellowship, and Hobson became a fellow of Christ's, and a lecturer in mathematics, in the autumn of the same year. He also did a good deal of private coaching. In 1883 he was made one of the first University lecturers in mathematics. But 'research' meant much less for a college and even for a university lecturer then than it does now, and Hobson wrote very little, and that of little importance, in his early years. His Royal Society memoir on spherical harmonics, which is now classical, and is the first of the papers on which his reputation rests, was not published until 1896.

Hobson's development as an original mathematician seems now to have been strangely slow. By 1903, however, he had moved a very long way; he had (largely as the result of intercourse with W. H. Young) acquired his interest in the modern theory of functions, and he had abandoned coaching in order to win leisure for research. From this time onward he changed rapidly into the Hobson whom we knew. In 1903 he became Stokes lecturer, a position which is now associated definitely with applied mathematics, and has been occupied, since Hobson held it, by Jeans, Fowler and Dirac; but Hobson was by then very plainly a pure mathematician. The first edition of his great "Theory of Functions of a Real Variable" appeared in 1907. In 1910, at the age of fifty-four, he succeeded Forsyth as Sadleirian professor, and he held this office until his retirement in 1931. He was still surprisingly vigorous, but, as well he might be, tured, and he admitted that he found retirement a great relief

Hobson received honours from many quarters He was elected to the Royal Society in 1893, served twice on the Council, and was Royal medallist in 1907 He was president of the London Mathematical Society in 1900–2, and received its de Morgan Medal in 1920 He was president of Section A of the British Association at Sheffield in 1910 He represented Cambridge at the Abel centenary in Oslo in 1902 He was an honorary doctor of six universities, and a member of various foreign academies But he said that no honour paid to him pleased him more than the dinner organised in his honour by the mathematical faculty of Cambridge less than a year before his death

He had many interests outside mathematics As befitted a man of his origin and training, and an intimate and long standing friend of James Ward, he was a keen philosopher Philosophy, indeed, was his strongest external interest, as one could judge from passages of his great book He was not a mathematical logician', but he was attracted by fundamentals, and was the first English mathematician to see the point of the discussions of the 'antinomies' and to recognise the importance of 'Zermelo's Axiom' It was therefore quite appropriate that he should have been one of the two or three mathematicians who have been invited to deliver Gifford lectures In these lectures, which were published as 'The Domain of Natural Science", in 1926, Hobson defends a rather extreme and rather abstract form of the 'descriptive' view of science

Hobson wrote five books in all His Trigonometry" is a well-known textbook which has run through many editions "Squaring the Circle', a reprint of six lectures delivered in 1913, is a popular book which may be compared with Klein's "Vorträge über ausgewahlte Fragen der Elementargeometrie" It is more solid than Klein, but is full of interesting information and most agreeably written, and makes one regret that Hobson did so little in the way of popular exposition The two remaining books, the huge treatise "Theory of Functions of a Real Variable", which occupied him from before 1907 until 1926, and the "Spherical and Ellipsoidal Harmonics", published only in 1931, though a great deal of it was written more than thirty years before, contain the record of most of the chief work of his life

The "Functions of a Real Variable" was published in 1907, at first as a single volume Young's "Theory of Sets of Points" had appeared one year before The modern theories of measure and integration were then almost new, and Hobson and Young were the first to introduce them to English readers. The classical theory of functions of a complex variable had been introduced into Cambridge by Forsyth, but real function theory was practically unknown To-day it is the part of pure mathematics that has been studied most intensively, and it is to Hobson and Young that the revolution is due The book, in its various editions, occupied Hobson for twenty years, and it was no doubt the central fact in Hobson's life, both for himself and for English mathematics The whole theory has expanded out of recognition, and very little of the first edition survives unchanged In particular, nearly all of Hobson's contributions to the subject were made after 1907 and appear only in the later editions The most important of these are to the theory of orthogonal series

It was in 1908 that Hobson published the first of his series of papers on the representation of an arbitrary function by a series of normal orthogonal functions In these papers he aims at obtaining conditions for the validity of such a representation "comparable in generality with the known sufficient conditions for Fourier series" The series in question include Sturm-Liouville series, Legendre series, and Bessel-Fourier series (and also Hermite and Laguerre series, which Hobson does not consider) The theory of integral equations, as developed by Hilbert and Schmidt, had led to a certain unification in the theory of these series, but only for functions of a severely restricted type, Kneser alone had obtained, for Sturm-Liouville series, reasonably general' conditions Here, and in other parts of the theory of orthogonal series, Hobson's work marks a big advance All this is set out systematically in its place in Hobson's book, which is, if any book ever was, a 'standard treatise', and is probably the most important book written by a modern English mathematician

The modern theory of functions of a real variable was in its infancy when Hobson began his work In England it was practically unknown, and rather derided There may perhaps have been a little excuse for the people who, like Greenhill, regarded it as a monstrosity, for there was still a faint air of mystery hanging about the elements and much of the superstructure was inelegant and more than a little tiresome Hobson and Young were the first English mathematicians to see the significance of the new ideas, and fought what must often have been a rather disheartening fight for their recognition Hobson lived to see real function theory the most highly developed mathematical discipline in Cambridge, a subject recognised even as a good Tripos subject', the most popular and paying subject in 'Schedule B The most commonplace Cambridge mathematician now has forgotten the superstition that it is impossible to be 'rigorous' without being dull, and that there is some mysterious terror in exact thought now we go to the opposite extreme and say that "rigour is of secondary importance in analysis because it can be supplied, granted the right idea, by any competent professional" All this we owe very largely to Hobson, but Hobson never quite understood how completely he had won his fight He always retained something of the air of the protagonist of an unpopular cause, he was a little too old to understand fully that everything that he had been fighting for had been achieved.

G H. HARDY.

News and Views

Sir Napier Shaw, F.R.S.

THE Council of the Royal Meteorological Society has made the *Quarterly Journal of the Royal Meteorological Society* of April 1934 a special "Shaw Number", in honour of Sir Napier Shaw's eightieth birthday. Sir Napier Shaw has done a great deal to educate English people to a recognition of the practical importance of meteorology. Under the title 'The March of Meteorology' he has contributed to his own number of the *Journal* a valuable collection of random recollections. This contribution is, besides being much else, an inner history of the evolution of the Meteorological Office during a period of about thirty years which followed his first connexion with official meteorology. One of Sir Napier's greatest personal contributions to meteorology has been connected with the thermodynamical theory built up around the idea of the Carnot cycle—a conception of an ideal heat engine often despised by students of engineering as being of no conceivable practical significance. In his "Manual of Meteorology" the general circulation of the atmosphere receives masterly treatment with the aid of this cycle and of the special diagrammatic framework with temperature and entropy as abscissae and ordinates which he has named the 'tephigram'. Although the full harvest from these ideas is perhaps still to come, they have thrown light on many atmospheric processes previously only very imperfectly understood. Another important contribution, and one that greatly advanced weather forecasting with the aid of synoptic charts, was the 'Life History of Surface Air Currents' (1906). This was the joint work of Sir Napier and his personal assistant R. G. K. Lempfert. This study, in his own words, "began the analysis of the motion of the air of a cyclonic depression into distinct currents which has been so fruitful in the hands of the Norwegian meteorologists". By the writing of these reminiscences at the age of eighty, Sir Napier Shaw shows the staying power characteristic of so many eminent scientific workers who became prominent in a period when the troubles of civilisation were less all pervading, and he reveals in them the broad outlook more common in a less specialised age.

Weather Observations

A SUPPLEMENTARY contribution to the same number of the *Quarterly Journal of the Meteorological Society* by Col. E. Gold follows Sir Napier's with the title "Incidents in the March, 1906–1914". This deals with a number of aspects of the work of the Meteorological Office not touched on by Sir Napier, among which may be mentioned the important contributions to the relationship between barometric pressure gradient and wind force, and to radiation in the atmosphere, made by the writer himself, and to the perhaps even more important pioneer investigations of G. I. Taylor in the subject of atmospheric turbulence, carried out during his tenure of the Schuster readership at Cambridge. It was during those years that the weather observations made at the health resorts were brought under official control, with the result that a reasonable degree of intercomparability has ever since existed in the tabular weather summaries published in most of the morning and evening newspapers, whereas formerly observers had almost unlimited opportunity for creating a false impression of the amount of sunshine to be expected by visitors favouring their own locality. The vexed question of the most suitable units to be used in British meteorology is also touched upon, a question that does not admit of easy solution seeing that the units that satisfy the meteorologist and are intelligible to the ordinary citizen of France and Germany, are not popular with those who through not having been educated in natural science, are unfamiliar with the C.G.S. system and the centigrade thermometer.

Water Supplies and Emergency Legislation

THE letter from Vice-Adm. Sir Percy Douglas, chairman of the British Association Research Committee on Inland Water Survey, which appeared in the *Times* of June 14, is an opportune reminder that something more than merely emergency measures to meet the present water shortage is necessary, if the administration of water supplies in Great Britain is to be placed on a sound and satisfactory basis. There may be in the popular mind a tendency to regard the recent appointment of an expert committee to advise the Ministry of Health on measures for dealing with the effects of the present drought as the sum total of all that is possible or due to be done in order to avert disagreeable and even disastrous consequences at any future time. But, as was pointed out in a leading article on the subject in NATURE of April 28, the root cause of the trouble lies much deeper, and will remain untouched by such superficial and temporary relief expedients as may present themselves for adoption during the existing crisis. In contradistinction to the practice prevailing in leading countries abroad, there is at present in Great Britain no official body charged with the duty of ascertaining available sources of supply and of gauging their extent and capacity, still less of supervising their distribution to the general advantage of the community. The necessity for a thorough investigation of the position in regard to both surface and underground yields is abundantly evident, and it would be foolish to disguise the fact, as Admiral Douglas so strongly emphasises, that "before it is possible to allocate the water supplies of the country an intensive and fully complete survey of the resources available is indispensable, and, however well planned the present emergency measures may be, the need for a systematic national survey remains".

British Science Guild

THE annual report of the Council of Management for the British Science Guild, 1933–34, presented at the annual general meeting on June 12, refers to the activities of the Parliamentary Science Committee, the headquarters of which are at present at the offices of the Guild The Committee is already supported by a number of scientific and technical associations, and active steps are being taken to secure the active interest of the majority of scientific societies The Guild continued during 1933 to make representations to the Government regarding the importance of continuing the work of the Research Association of British Rubber Manufacturers, which the Committee of the Privy Council has now agreed to assist by an annual grant for five years A preliminary memorandum on the development and finance of industrial research has been issued by the committee set up jointly with the Association of Scientific Workers, and arising out of a meeting of the Committee questions have been raised in Parliament regarding expenditure on wireless research by the Post Office and British Broadcasting Corporation The question of adopting the French system of automatic time transmission by telephone has been raised with the Postmaster General and is under consideration Attention has also been directed to the importance of scientific research in connexion with the newly formed marketing boards

LAST year a lecture was instituted by the Guild to direct attention to the importance of research and the utilisation of its results in the service of mankind Largely through the generosity of Lord Melchett and Lord Weir, there has now been instituted a series of such research and development lectures designed especially to bridge the gap that exists between those engaged in national affairs and the man of science Abstracts of the two lectures of this series given this year by Sir William Bragg on Refrigeration" and by Lord Rutherford on "Helium and Other Rare Gases" are appended to the report The report directs attention to the unsatisfactory condition of the Guild's finances There is a deficit of about £400 a year, but thanks to the offer of a member of Council it has been possible to arrange to utilise capital during the next three years while a three year plan is put into operation including a programme similar to that of 1933, every possible assistance to the Parliamentary Science Committee and a sustained effort to increase the annual income

Science and the Nazis

GERMANY'S latest regulation affecting scientific inquiry may be the logical consequence of principles accepted in that country, but is none the less curious Herr Julius Streicher's deputy, according to a correspondent in the *Times* of June 13, has issued an order prohibiting scientific lectures on racial questions, since they have a 'diluting and distorting effect on the Nazi *Weltanschauung*' Professional men of science, it is added, are not equipped with the necessary knowledge and honest conviction and their lectures are, therefore, a danger to the true Nazi creed If this statement has any basis at all in fact, it can only mean that German men of science are either too honest or have too keen a sense of the incongruous to accept and reproduce the official Nazi travesty of racial history with which Herr Hitler has hypnotised himself and the German masses The entire suppression of lectures in one branch of study, however, enforces the lesson that the relation between science and State action is one of extreme delicacy, and that any attempt to drive politics and science in double harness in the interest of a theory of racial or social regeneration, as has been done in Germany, and was attempted in framing the immigration laws of the United States, risks the suppression of honest, but unpopular inquiry It is surely inconsistent that the advocates of racial purity in their own part of the world, in their further programme for dealing with Jews, should suggest that the thirty millions of this people should be quartered among the inhabitants of Madagascar

Central American Hurricane and World Rainfall

WHILE a large area in North America has been suffering from unprecedented drought, a part of Central America has recently experienced a very severe hurricane although it is early in the hurricane season A very small proportion only of the tropical storms of the West Indies and neighbouring mainland occur in the first half of June the time of maximum frequency being not far from the autumnal equinox. The storm in question appears to have passed northwestwards across Salvador before reaching the Mexican coast, it was accompanied by exceptionally heavy rains that caused serious floods To these floods is attributed the great loss of life, variously estimated at a thousand and at two thousand or more In the *Times* of June 13 it is stated that the Honduran town of Ocotepeque, near the Guatemalan border, was entirely destroyed It may be recalled that in 1933 there was a record number of West Indian hurricanes This early and disastrous opening for 1934 seems ominous When rainfall is deficient in middle latitudes there is no more likely place for finding an excess sufficient to keep the world's fall at about its normal amount than in the hurricane belt, and the coincidence of exceptional drought in North America and exceptional storminess in the West Indies may possibly not be fortuitous Approximate constancy of the world's total fall cannot of course, be proved or disproved in the absence of exact measurements over the oceans, but it may be noted that the sun's radiation tends to appear more constant the more exactly it is measured which seems to suggest that the average rainfall for the year—indirectly dependent, doubtless, on solar heat—may not vary greatly

Archæology and the Economic Crisis in the United States

EXCAVATIONS on a number of archæological sites in various States, undertaken as part of the emergency measures for the relief of unemployment under the Civil Works Administration in the United States, have produced material which, according to a statement issued by the Smithsonian Institution of Washington, it will take years to work out in detail So satisfactory have been the results that in several States the work is to be continued by a State subvention now that the grant of the Civil Works

Administration has been exhausted Among the more successful investigations is the exploration of two Indian village sites on the shores of the dry Buena Vista Lake Kern County, California Of these villages one was entirely prehistoric and may go so far back as the beginning of the Christian era. It is hoped to check the dating by the ring marks of wooden posts recovered from the site The second village was occupied by Yokut Indians as late as 1772, when it was visited by Spanish missions; but by 1825 it had entirely disappeared It had evidently been occupied for a long time as no less than seven distinct lake terraces were uncovered in the course of the excavation From a cemetery on the near by hillside 350 skeletons were obtained In the earlier village bodies were buried under the floors of the houses The flint points found here were cruder than those of the later village settlement Among the results obtained under this scheme of exploration in other States mention may be made of a mound near Bradenton in Florida which revealed for the first time the character of a Florida mortuary temple the identification of a village of the Hitchiti Indians of the Creek Confederacy in mounds near Macon Georgia, the identification of Guasili visited by de Soto in North Carolina and the discovery of house structures and much pottery in the Shiloh National Park Tennessee

Excavations at Gaza 1933–34

OWING to the operation of the Antiquities Law of Palestine none of the objects excavated at Gaza during the last season by the British School of Archæology in Egypt has been allowed to leave the country Sir Flinders Petrie accordingly announces that the usual exhibition of antiquities at University College London will not take place this year Lantern lectures on the year's work of the School were delivered at the College on June 14 16 and 19 The main work of the expedition of which a preliminary account was given in a letter from Sir Flinders Petrie in the *Times* of June 14 was directed to clearing an area of about four acres along the river side from which a large number of objects was recovered One of the most noteworthy results was the large number of gold ornaments obtained from burials and from goldsmiths hoards These included ear rings of granular goldwork of unique type The prominence of Irish goldsmiths work is again obvious On the other hand in a burial of a little girl, the gold work is on the Egyptian weights standard and it included pendants of hippopotamus and of Horus The most marked feature of the finds as a whole is their varied provenance pointing to the importance of this ancient port, to which the presence of more than 200 hæmatite weights testified Persian trade is indicated not only by a dagger from Lauristan but also by an abundance of Persian weights in number half as many as those from Egypt Relations with the Caucasus are indicated by daggers of bronze, while the use of the toggle pin, of which specimens were found in all the deposits, belongs to the Caspian The most considerable building unearthed is of middle Hyksos age and may be a temple

Infra-Red Lights and Aviation

HOPES that infra red light might be usefully employed by aviation in foggy weather have, according to Science Service, of Washington, D C, not been fulfilled Dr Irving Langmuir, at a recent meeting of scientific workers and engineers called by the U S Bureau of Aeronautics said that there is no known source of infra-red radiation of the wave lengths necessary for penetrating fog The discovery of a way to produce such radiation would be a stroke of genius and is not likely to occur in the course of routine experimentation The scientific workers present also discouraged experiments by the Government on proposed schemes for the dissipation of fog by the use of a Tesla coil or other apparatus Similar plans have been often suggested and it is now known that it is theoretically impossible for them to work well enough to be of practical value Dr W J Humphreys said that methods based on scientific principles are much too expensive to be used in aviation Two possible solutions of the problem of fog landings were approved by the meeting and intensive research was urged along these lines The first solution was to use radio signals By the use of suitable instruments his position with reference to the flying field can easily be found by the aviator It is now possible to use radio signals the wave lengths of which are not greater than ten metres and this is the possible error of the method It is not necessary to wait until shorter wave lengths are available The other solution favoured was a device similar to that used by ships to determine the depth of the sea beneath them It is quite possible for a suitable instrument to pick up an echo from the ground and show on a dial the height in feet of the plane above it

Refrigeration

IN connexion with the Refrigeration Exhibition now being held at the Science Museum South Kensington a guide has been prepared by Messrs T C Crawhall and B Lentaigne which in addition to describing the exhibits gives accounts of the scientific principles which underlie refrigeration and of its historical development (pp 28 + 2 plates. London H M Stationery Office, 1934 6*d* net) A further publication which will be welcomed by all those engaged in the refrigerating industry is the Five Year Bibliography' of the subject which has been prepared by Mr H T Pledge, of the Science Library (pp 97 London H M Stationery Office, 1934 2*s* net) It is a foolscap pamphlet of 97 pages with the typed entries in two columns under the decimal classification numbers 621 56 to 58, with a short section on air conditioning under 697 9 Under Refrigerants 621 564 there are 8 pages of entries which include between eighty and ninety dealing with dry ice or solid carbonic acid—621 564 22—under its various names of neige carbonique, trockenes ghiaccio secco droog Ijs, glace seche, Cold, Kold Trol, Cardice, Drikold and others The fact that the Science Library has prepared more than 120 bibliographies of this type on subjects varying from

Bessel functions to the habits of lizards seems very little known, and much time has in consequence been wasted by research workers in collecting information on subjects in which bibliographies were already in existence

Street Lighting

ILLUMINATING engineers are beginning to agitate for national control of the lighting of roads and streets In the *Electrical Review* of June 8, C W Sully points out that boroughs and urban councils in Great Britain are granted powers regarding street lighting by the Public Health Act of 1875 and that rural districts exercise their powers under the Lighting and Watching Act of 1833 The public lighting of all our thoroughfares to-day is controlled by Acts published either sixty or a hundred years ago Our population has nearly trebled since 1833 and has increased by more than seventy per cent since the last Act became law There were no fast moving vehicles on our roads sixty years ago—there are now two million licensed automobiles The existence of vast numbers of cinemas and also of greyhound racing tracks encourages pedestrians to use the streets after dark Yet much of our highway lighting is mounted on similar posts spaced at the same distance apart as when our road vehicles were fitted with lanterns carrying candles The candle power of the lights have been increased a hundred fold in order to lessen the risk of accidents but in many roads the lighting is very 'patchy', the lamps acting mainly as beacon lights It is wasteful to employ large units without suitable directive fittings to ensure a uniform distribution of the light The new British Standard Specification makes a special feature of this by setting out a spacing ratio for street lights which produces a more uniform illumination In general this entails altering the height of the posts It would be advisable if the Government would allot to one of its numerous departments the task of specifying the minimum light to be provided on the various roads which it has already classified It appears that new legislation is required to deal with this important matter

Some Aspects of the Vertebrate Brain

In his presidential address before the Linnean Society of New South Wales on March 28, Prof A N Burkitt outlined progress in our knowledge of the structure and workings of the brain The present lopsidedness of our knowledge, so amazing in the physical and chemical world and so backward as regards the very instrument which has created human civilisation, is the cause of much of the discontent and difficulties of our present age. Recent work upon the sense organs and the impulses they transmit to the brain, and some idea of how closely parallel to the physical reality these impulses may be, was discussed, partly in relation to philosophical problems The bearing of the evolution of the sense organs upon the evolution of the brain, so ably outlined by Elliot Smith, was briefly mentioned The importance of the recent discovery that the emotional aspect of life is associated with the activity of a special part of the brain, the thalamus, distinct and separate from the great thinking and discriminatory apparatus, the cerebral cortex, was emphasised, and suggestions were made as to the possible bearing of this knowledge upon the Freudian hypothesis Finally an attempt was made to suggest some inkling of the physiological phenomena that occur in the brain during conscious thinking in all its myriad aspects, also the mechanisms concerned in expression and the control of muscles, together with the evolution of these controlling mechanisms and muscles were briefly outlined

Organisation of Production

UNDER the title Prohibiting Poverty', a pamphlet by P M Martin, written and published by P M Martin Winter Park Florida, outlines a plan for obtaining economic security, based on the view that the prime purpose of organised society is to enable everyone to get a living The plan, described as the National Livelihood Plan, proposes to separate necessaries from luxuries and to deal with them in separate departments of government on different principles The production of necessities is to be organised under a new national organisation known as the Commons, the function of which is to produce and distribute a basic livelihood in necessities to the entire population This organisation would operate without money distributing goods as produced without selling them It would be recruited compulsorily by the whole youth of the nation from school leaving age and would utilise the full advantages of scientific discovery in increasing industrial output and efficiency After eight years service, the Commoner would pass into the Capitals, in which the existing capitalistic organisation of society would persist, limited, however, to the production of luxuries and in which his previous labours have earned him or her a free distribution for life from the Commons of the basic necessities of life The Commons would be directed by a salaried body of technical experts, men of science and investigators concerned with the continual development and full utilisation of improved methods of production

Animal Breeding in the British Empire

THE Imperial Bureau of Animal Genetics has issued a bulletin of 47 pages by Dr F Fraser Darling on animal breeding in the British Empire obtainable from Oliver and Boyd, Edinburgh, or 33 Paternoster Row, E C, at 1*s* It summarises the present position and work in progress in the breeding of farm animals in all parts of the Empire The first part deals with Great Britain and the Dominions, where conditions are mainly temperate, the second part with India and the Colonies, which are largely in the tropics The more practical aspects of the breeding of horses, cattle, sheep, pigs and goats are considered Reference is made to such recent developments as sperm storage for horse insemination, and the fact that breeds of pigs differ in the number of ribs and hence in their value for bacon Useful information is given regarding sheep breeding in Britain, Canada, Australia, New Zealand and South Africa, and the varying problems each country has to face We learn that the world's record for butter-fat production —1,614 lb in a year—is held by an Australian Shorthorn, that Romney Marsh sheep are successful in New Zealand, and that camel breeding is developed by Government in the Sudan Zebu cattle and buffaloes have been introduced from India into the West Indies, Tanganyika and British Guiana Cattle suitable for the tropics can probably be produced by crosses between zebu and certain European breeds Such crosses between zebu cows and Friesian bulls have produced a satisfactory breed in Trinidad, but Krishna Valley zebu in Tanganyika crossed with Devons or Aberdeen Angus give intractable animals unsuitable for domestic uses

National Institute of Agricultural Botany

THE fourteenth report of the National Institute of Agricultural Botany records considerable progress in the selection and multiplication of improved crops Exhaustive tests of yield of many farm and garden plants have been made in different districts and authoritative comparisons of varieties are now available Considerable research is being devoted to problems of seed testing, and a large number of routine tests have been made for other investigators The classical potato trials at Ormskirk, Lancs, seem to have suffered from severe climatic conditions but the work on potato synonyms progresses satisfactorily, and should do much to protect the farmer and gardener from unfair exploitation The head office of the Institute is in Huntingdon Road Cambridge, and a very close co-operation is maintained with related organisations

Ichthyology in the United States

THE twentieth anniversary number of *Copeia* (No 4, December 1933 American Society of Ichthyologists and Herpetologists), which deals with fishes, reptiles and amphibians, is dedicated to its founder, John Treadwell Nicholls In it are included many interesting and valuable papers notable among them being ' Deep Sea Stomiatoid Fishes by William Beebe, in which one new genus and eight new species are described from the Bermuda Oceanographic Expeditions of the Department of Tropical Research of the New York Zoological Society These were all taken within the eight mile circle, the centre of which is at lat 32° 12′ N long 64° 36′ W, 9½ miles south-south west of Nonsuch Island, Bermuda The barbels of some of these fishes are very peculiar; one of them, belonging to *Ultimostomias mirabilis* gen et sp.nov, has a barbel measuring 417 mm in length (more than ten times the length of the fish itself) Other papers on fish are by Albert Eide Parr, George S Myers, E W Gudger and C M Breder, Jr A new snake from Panama is described by E R Dunn and there is an interesting article on the immunity of rattlesnakes to their venom by A A Nichol, Volney Douglas and Lewellyn Peck Other papers are on the nests and young of the Allegheny salamander, the ophidian generic names *Ahaetulla* and *Dendrophis*, secondary sexual characters of *Bufo melanostictus*, and *Pseudemys troostii-elegans* complex a case of sexual dimorphism

Strength of Spirits

As is well known the Finance Act of 1915 provided that where by reason of the high temperature or strength of spirits the ordinary Sikes hydrometer was not applicable, the strength may be ascertained by means of the supplemental Sikes *A* hydrometer using tables identified as II and IV prepared by the late Sir Edward Thorpe when principal of the Government Laboratory Under the Strength and Weight of Spirits Ascertainment Regulations 1930 when the same conditions of high temperature or strength apply, the use of a further supplemental Sikes *B* hydrometer is permitted When this is used without the poise marked *A* attached, Tables V and VI prepared by Sir Robert Robertson are applicable Tables II, IV, V and VI have been issued under the authority of the Commissioners of H.M Customs and Excise in one volume at 2*s* 6*d* (London H M Stationery Office) the ordinary tables I and III are printed in a separate volume The tables cover temperatures from 30° to 100° F

Institution of Petroleum Geologists

THE summer meeting of the Institution of Petroleum Technologists will be held in London at the Royal Society of Arts on June 28–29 The programme consists of a series of papers, available in advance, on general topics which will be submitted for discussion The subjects of the first day's discussions are the relation of oil and coal to the petroleum industry measurement of oil in bulk, and the format of the Institution's *Journal* The second day is being given to a series of reports on the progress of naphthology, the Refining and Chemical Section under the chairmanship of Dr F H Garner, will occupy the morning session, while the Field Technology Geology and General Sections, under the chairmanship of Mr A Beeby Thompson, will take up the afternoon session During the course of the annual dinner on June 29 the Redwood Medal of the Institution will be presented to Dr David White, of the U S Geological Survey, who is known for his studies in palæobotany This medal is awarded biennially, and is given for contributions to our knowledge of petroleum technology

Rockefeller Medical Fellowships

THE Medical Research Council announces that, on behalf of the Rockefeller Foundation of New York, it has made the following awards of travelling fellowships for the academic year 1934–35: Mr I Aird, demonstrator in anatomy, University of Edinburgh, and clinical tutor in surgery, Royal Infirmary, Edinburgh, Mr I A Anderson, house physician, Royal Infirmary, Aberdeen; Prof E G Oastler, professor of physiology, St Mungo's College, Glasgow, and assistant physician, Royal Infirmary, Glasgow, Mr W H Owles, resident medical registrar, Queen's Hospital, Birmingham; Dr H L Sheehan, lecturer in pathology, University of Manchester, Mr C Wilson, assistant in pathology, London Hospital These fellowships are awarded to graduates who have had some training in research work either in the primary sciences of medicine or in clinical medicine or surgery, and who are likely to profit by a period of work abroad before taking up positions for higher teaching or research in the British Isles All the fellows appointed this year will work at centres in the United States

International Council of Scientific Unions

THE International Council of Scientific Unions will hold its triennial meeting at Brussels on July 9–14 At the last meeting, in 1931, the title of the organisation was changed from that of the International Research Council to the present one and the statutes were revised to give greater freedom of action to the international unions On the present occasion each of these unions, representing astronomy geodesy and geophysics, chemistry, scientific radio transmission, physics, geography and biological science will communicate an account of its activities during the past three year period Addresses will also be given by Dr D la Cour on the International Polar Year 1932–33, its aims, methods and some preliminary results, by General G Perrier, on recent international determinations of longitude, by Dr E P Hubble, on the exploration of space and by Prof H R Kruyt on electricity and hydration of colloids

Announcements

A MOSELEY Research Studentship of the Royal Society has been awarded to Dr Barnet Woolf for research on bacteriology and immunology

SIR HAROLD HARTLEY, chairman of the Fuel Research Board of the Department of Scientific and Industrial Research, is inviting a number of scientific workers and industrialists to inspect the work in progress at the Fuel Research Station, River Way Blackwall Lane, East Greenwich, S E 10, on June 25 The function will be generally similar to the annual visitation of the National Physical Laboratory, but it is the first of its kind to be held at the Fuel Research Station.

A SCIENTIFIC committee to assist the director, Dr Louis Martin, has been formed at the Institut Pasteur, Paris, consisting of MM J Bordet, director of the Institut Pasteur of Brussels, and Nobel prizeman; G Bertrand and F E P Mesnil, members of the Institut de France and Académie de Médecine, C J H Nicolle, professor at the Collège de France and Nobel prizeman, A J E Yersin, director of the Instituts Pasteur of Indo-China, and A Borel, director of the Institut d'Hygiène at Strasbourg Further members may be appointed later

AT the seventeenth annual meeting of the American Society of Ichthyologists and Herpetologists, held in New York on May 10–12, the following were elected officers for the ensuing year: *Honorary Presidents*, Leonhard Stejneger and John T Nichols; *President*, Carl L Hubbs, *Vice Presidents*, Dr E W Gudger, Dr Francis Harper and Clifford Pope; *Secretary* M Graham Netting; *Treasurer*, A. W Henn, *Editors*, Carl L Hubbs and Helen T Gaige The next meeting of the Society will be held in Pittsburgh in May 1935

MESSRS A GALLENKAMP AND CO, LTD (17–29 Sun Street, and 1–3 Clifton Street, London, E C 2) announce the introduction of a new type of all glass syringe for medical use It is constructed of pyrex glass in various sizes, and is provided with stainless steel needles Copper coated glassware—beakers, flasks etc —is also supplied by this firm The copper is electrolytically deposited on the outside and the advantages claimed are rapid distribution of heat and saving of the liquid should the glass crack

APPLICATIONS are invited for the following appointments on or before the dates mentioned —A lecturer in mathematics and physics at the Portsmouth Municipal College—The Registrar (June 25) Part time lecturers and instructors in engineering welding, electrical installation etc at the Willesden Technical College Denzil Road London N W 10—The Principal (June 25) A professor of botany in the Egyptian University—The Dean of the Faculty of Science, c/o The Director, Egyptian Education Office 39, Victoria Street, London, S W 1 (June 25) A head of the Women's Department in the Wolverhampton and Staffordshire Technical College—The Clerk to the Governors Education Offices, Wolverhampton (June 25) A lecturer in botany and a lecturer in zoology at Armstrong College, Newcastle upon Tyne —The Registrar (June 26) A teacher of chemistry at the Doncaster Technical College—The Secretary, Education Offices Doncaster (June 27) An assistant civil engineer to the Air Ministry—The Secretary (S 2) Adastral House, Kingsway, W C 2 (June 28) A metallurgist to the British Non Ferrous Metals Research Association—The Secretary, Regnart Buildings, Euston Street London, N W 1 (June 30) A lecturer in science at the Gordon Memorial College, Khartoum—The Secretary (Sir/C A), Board of Education, Whitehall, London, S W 1 (June 30) An assistant lecturer in electrical engineering at University College, Nottingham—The Registrar (July 2) A research assistant in soil science in the Department of Agriculture, University of Cambridge—The Secretary of the School of Agriculture (July 2) A field officer for investigations on Braxy like diseases of sheep and a junior research officer for investigations on swine erysipelas at the Institute of Animal Pathology, University of Cambridge—The Director (July 7) A professor of social anthropology in the University of Cape Town—The High Commissioner for the Union of South Africa, Trafalgar Square, London (Aug 15) A Regius professor of midwifery in the University of Glasgow—The Private Secretary, Scottish Office, Whitehall, London, S W 1 A chemist at the East Malling Research Station, Kent—The Secretary

Early History of Mendeléeff's Periodic Law

THE statement appears in NATURE of April 28, p 656, that Mendeléeff's first table, published in 1871 bears a remarkable resemblance to that of the present day As a matter of fact, Dmitri Ivanovitch Mendeléeff began his investigations on the correlation of chemical properties with the atomic weight of elements in 1868, and succeeded in evolving the periodicity of this relationship at the end of that year He printed the first periodic table in the middle of February, 1869 as follows

An attempt of a system of elements
based on their atomic weight and chemical resemblance

			Ti = 50	Zr = 90	? = 180
			V = 51	Nb = 94	Ta = 182
			Cr = 52	Mo = 96	W 186
			Mn = 55	Rh = 104 4	Pt = 197 4
			Fe = 56	Ru = 104 4	Ir = 198
			Ni = Co = 59	Pd = 106 6	Os = 199
H = 1			Cu = 63 4	Ag = 108	Hg = 200
	Be = 9 4	Mg = 24	Zn = 65 2	Cd = 112	
	B = 11	Al = 27 4	? = 68	Ur = 116	Au = 197?
	C = 12	Si = 28	? = 70	Sn = 118	
	N = 14	P = 31	As = 75	Sb = 122	Bi = 210?
	O = 16	S = 32	Se = 79 4	Te = 128?	
	F = 19	Cl = 35 5	Br = 80	J = 127	
Li = 7	Na = 23	K = 39	Rb = 85 4	Cs = 133	Tl = 204
		Ca = 40	Sr = 87 6	Ba = 137	Pb = 207
		? = 45	Ce = 92		
		?Er = 56	La = 94		
		?Yt = 60	Di = 95		
		In = 75 6	Th = 118?		

Mendeléeff prepared his first essay, 'Correlation of the Properties with the Atomic Weight of Elements', early in March, 1869 intending to communicate it to the Russian Chemical Society (which was founded on October 26 1868) at the meeting on March 6 Illness prevented him from attending and the paper was read at his request, by my father, Nikolai Aleksandrovič Menschutkin at the time professor of analytical chemistry at the University of St Petersburg Mendeléeff's memoir was printed in the first volume of the *Journal of the Russian Chemical Society* (1869, pages 60–77) it contains the same table as that printed above, the enunciation of the periodic law and the deductions (*a*) that the atomic weights of some elements must be altered, to fit into the table, (*b*) that undiscovered elements exist, filling up the vacant places of the table

Continuing his work on that subject, D I Mendeléeff communicated further results on August 23, 1869, in a meeting of the Second Congress of Russian Naturalists in Moscow This communication was published in the Transactions of the Congress (pages 62–71) under the title 'On the Atomic Volume of Simple Bodies" Mendeléeff recognised the importance of this periodically changing property of elements for their classification, and gave the following table— the prototype of all later periodic tables

Li	Be	B	C	N	O	F			
Na	Mg	Al	Si	P	S	Cl			
K	Ca	—	Ti	V	Cr	Mn	Fe	Co	Ni
Cu	Zn	—	—	As	Se	Br			
Rb	Sr	—	Zr	Nb	Mo	—	Rh	Ru	Pd
Ag	Cd	—	Sn	Sb	Te	I			
Cs	Ba	—	—	Ta	W	—	Pt	Ir	Os

In the text, this table is completed by the heavy metals Au, Hg, Tl, Pb, Bi Elements, the atomic weights of which were not known with any degree of certainty, such as In, Th, U, Ce, are left out

I do not propose further to follow up Mendeléeff's work here, only mentioning his communication at the meeting of the Russian Chemical Society of December 3, 1870, in which he divided the elements into the periods, rows and groups, now familiar to all students of chemistry He also made here detailed predictions of the properties of undiscovered elements, which were verified in the years 1875–86 through the discovery of gallium scandium and germanium

Thus Mendeléeff s periodic table actually antedates his periodic law and received its modern form in 1869 not in 1871

Mesomerism and Tautomerism

THE recognition of valency exchange degeneracy as a matter of primary importance in relation to the energy[1] and reactivity[2] of organic molecules makes it the more necessary clearly to indicate the nature of the conception It envisages both completely and incompletely degenerate states collectively called 'mesomeric' states, and these states are described by first setting up unperturbed structures', which correspond to classical chemical formulæ but (according to the theory) not exactly to reality and then 'correcting' these structures by supposing them to undergo a perturbation', the nature of which may be indicated by auxiliary symbols

The idea appears to have gained some ground that the conception of the mesomeric state is unnecessary, that the unperturbed structures are all that exist, and that these pass into each other like tautomerides but much more rapidly, the great frequency of interchange accounting for the energy effect If this view has arisen from the use of the expression resonance, a long accepted synonym for exchange degeneracy, then it must be admitted that an analogy has been suggested which was never intended (the real analogy underlying this term is a mathematical one)

It is a characteristic of tautomeric systems that forms exist which clearly correspond to separate molecular states, because each molecule spends the whole of its life partly in one form and partly in the other, and only a proportionately quite insignificant time in the actual process of transition If, however, in any of the most typical cases of 'resonance', we attempt to interpret resonance energy as a tautomerism of unperturbed states, the frequency of interchange which it is necessary to assume in order to account for the energy effect is often so great as to require that the molecules must occupy their time in changing, and cannot remain quiescent for significant periods in either of the assumed states, in other words, the term 'state' loses its meaning in reference to the only states which this theory recognises The assumed frequency of valency interchange is, indeed, of the same sort of magnitude as the frequencies which are attributable generally to combined electrons, aside altogether from valency resonance. There can be no physical distinction, therefore, between resonance vibrations and other electronic vibrations, and it follows that the unperturbed structures, in which the resonance vibrations are absent by assumption, are unreal they are of the nature of intellectual scaffolding, and only the mesomeric state is real The additional electronic energy associated with resonance naturally implies an altered wave function but the reasons why we do not associate this energy difference with a definite frequency along a definite path are quite analogous to the reasons for not reverting to Bohr orbits in the description of molecular structures generally[3]

The energy evidence proves this point[1] and the results of infra red spectroscopy and dipole moment measurements supply important confirmation[4] it may, however, be worth noting that the thesis is necessary also on quite elementary chemical grounds[2] For this purpose any simple problem of reactivity in which mesomerism plays a leading part will serve and we may, for example consider the fact that aniline is a weaker base by about a million fold than a primary alkylamine such as methylamine or *tert* butylamine The neutral unperturbed structure for aniline, $NH_2{-}C_6H_5$ requires a basicity of about the same order of magnitude as that of a primary alkylamine, and the three dipolar unperturbed structures which may collectively be represented $\overset{+}{N}H_2{=}\overset{-}{C}_6H_5$, all require a basicity (for ammonium salt formation) of zero If we were to try to account for the small basicity of aniline by postulating a tautomerism too rapid for direct detection, between these unperturbed structures considered as molecular states, we should have to assume that the substance exists practically entirely in the betaine forms—an obviously untenable hypothesis The only way to avoid this difficulty would be to increase the assumed rate of interchange to such a degree that the molecules would almost always fail to remain in the more basic form, $NH_2{-}C_6H_5$ for the duration of a molecular collision, for if this were true even a high instantaneous concentration of NH_2 C_6H_5 molecules would fail to produce a corresponding amount of basic reactivity A supposition of this kind however is tantamount to discarding altogether the conception of unperturbed forms as molecular states and adopting in its place the idea of a state distinct in properties from either of the states originally assumed

Thus mesomerism and tautomerism are different concepts and we must ascribe to the mesomeric state something more than a titular position in the physics and chemistry of unsaturated structures[5]

Kinetics of Reactions of Heavy Hydrogen

THE publication, recently, of two notes[1] concerning the reaction of heavy hydrogen and oxygen at elevated temperatures suggests that it may be of interest to mention briefly experiments which have been in progress in this laboratory during the past few months and which have had for their object the possible confirmation or elucidation of the mechanism of some chain reactions A search has also been made for examples of reactions involving the quantum mechanical leakage of H and of D atoms through potential barriers

At room temperatures and with excess hydrogen H and D atoms produced photochemically react with oxygen molecules at exactly the same speed With excess oxygen under the same conditions, there is a difference (30 per cent for a 66 per cent mixture) which is due solely to collision frequency factors between the mercury atoms and the H_2, HD, D_2 and O_2 molecules Similarly in the hydrogenation of ethylene and of nitrous oxide and in the reduction of copper oxide by atoms there is no difference in the velocity of reaction of the two isotopes

At higher temperatures in the hydrogen – oxygen reaction where chains are propagated separation occurs for example at 339° C With a pressure of 5 mm of a 2 1 mixture the ratio of rates of reaction for a 66 per cent diplogen mixture is 1 26 1 falling to 1 10 1 at 421° The difference is probably due to the participation of hydrogen molecules in the chain In the hydrogen – nitrous oxide reaction where chains are also propagated and the slowest now involves the reaction of a hydrogen atom there is no separation whatsoever With ethylene there is no separation and no chain propagation Copper oxide is reduced at different speeds with heavy and with ordinary hydrogen molecules the separation decreasing with increasing temperature, for example, the ratio of rates for a 47 per cent mixture are at 156° 1 26 at 201° 1 17 and at 269° 1 13

So far as these results indicate therefore the statement may be made that H and D atoms, even in reactions requiring considerable activation react at the same speeds in the gas phase whereas, if the rate determining step involves a molecule or the interaction of the atom adsorbed on a surface, as in the reduction of copper oxide the greater reactivity of hydrogen is due mainly if not wholly to the difference in zero point energies of the H and the D molecules

Ionospheric Height Measurement in the United Provinces of Agra and Oudh (India)

THE measurements of the height of the ionosphere have been taken in India for the last three years by Prof S K Mitra[1] and his students in Calcutta India is such a big country that the measurement at Calcutta alone cannot serve as representative values for the whole of India Early this year therefore it was decided to take measurements at Allahabad, and the preliminary observations are summarised below

The transmitter employed was of the conventional type sending 50 pulses per second of $3\ 8 \times 10^{-4}$ seconds duration Through the ready co-operation of Rai Amarnath Agarwal—to whom our thanks are due—the receiving equipment was located at his residence in Daraganj, a distance of about 2 miles from the transmitter The echoes were visually observed on a cathode ray oscillograph

On May 13 between 18 30 and 20 00 I S T, the height of the *E* layer was found to be 135 km and usually four multiple reflections and sometimes as many as six were detected Between 19 00 and 19 30 I S T the intensity of the first reflection often shot up to 2 3 times that of the ground wave but this unusual intensity lasted for about 3–5 seconds Between 19 15 and 19 20 the intensity of the second reflection was found on two occasions to be from 3 to 4 times that of the ground pulse although the intensity of the first reflection was only about half that of the ground pulse

Further observations were taken in the early morning hours (5 30–6 30) of May 14 The height of the *F* layer was found to be 270 km in the beginning and gradually fell to 250 km Four reflections were usually present the first was always the strongest its intensity sometimes becoming as great as that of the ground pulse

The distance between the adjacent reflections was always the same thus showing the presence of multiple reflections between the earth and the ionosphere Messrs Mitra and Rakshit[2] could detect the multiple reflections one hour before the sunset but we have been able to observe multiple reflections in the morning as well

It appears from our observations that the *E* layer is predominant during the evening and sunset period and during the night the ionisation in the lower layer becomes too small and up to about half an hour after sunrise reflections from the *F* layer are observed

The work is being continued

Effect of Thunderstorms upon the Ionosphere

Morgantown West Virginia U S A is situated on the western slope of the Appalachian Mountains which run in a south westerly direction These mountains cause a great deal of variation in the signal strength of the broadcasting stations along the Atlantic coast as received in Morgantown and also affect the short wave band

One of my students Mr A W Friend has been operating a short wave station here for many years He informs me that on account of the high hills near his home his station cannot be heard in the south eastern sector of the United States *except after a thunderstorm* He can hear the amateur short wave stations in the southern States but they can never hear him if the weather is fine but after a thunder storm he can remain in contact with them for several hours

At my suggestion Mr Friend made out the following table from the log of his station It shows the times at which the stations were able to hear him

Station	Date	Time	Freq Kc.	Output, watts
Greensboro N C	April 29 1931	11 16 p m	7 000	12
Wilmington N C	April 30 1931	6 15 p m.	7 000	12
Marion Ala	June 2, 1931	12 55 a.m.	7 000	12
Atlanta, Ga	June 5 1931	10 38 p m.	14 000	8
Salisbury N C	Aug. 24 1931	1 05 a m.	7 000	15

These stations are all located several hundred miles south or south east of Morgantown and two way communication was never possible under normal atmospheric conditions Mr Friend's observations strongly support Prof C T R Wilson s theory that some of the ionisation in the ionosphere is due to thunderstorms Not all of the abnormal ionisation arises from local thunderstorms for I have often observed increased ionisation in the *E* layer after sunset during the winter months when there were no thunderstorms within a thousand miles

Static Charge on a Galvo-Millivoltmeter

In Nature of May 19 Mr H A Bromley mentioned the trouble he had experienced owing to the needle of a millivoltmeter being attracted by the electrostatic charge on the surface of the glass window of the instrument

This trouble has been known for many years and is usually overcome by wiping the glass with a cloth on which there is a slight trace of glycerine This so effectually gets rid of the trouble for a little while —when the process has to be repeated—that I think readers of Nature may be glad to know of it

Velocity of Light

The chief objection which can be raised at the present time to the hypothesis of a continuous decrease of the velocity of light is that it is only justified if we admit that the work of Michelson and Newcomb in the last century is unreliable Now their determinations made in 1882 agree so closely although made independently with different instruments and a somewhat different technique that, in my opinion they are probably very accurate

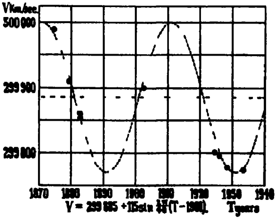

Fig 1

Seven years ago I pointed out that the problem would be simplified if it were admitted that the velocity fluctuates[1] The arbitrary rejection of some observations would not then be required there having been a decrease in 1874–1883 and another in 1902–1934 An irregular variation, however is of little scientific value it is so easy to fit one to the observations a regular periodic variation on the other hand, if it fits all the observed values without omitting any, would be much more convincing than a linear law which ignores one third of the data The remarkably close agreement of Edmondson's sine law of variation[2] with the observations cannot be fully appreciated without a graphical representation such as that reproduced as Fig 1, it is significant, particularly because of its simplicity and because the period is the longest possible a sinusoid which would 'pick up' Perrotin s value artificially by a multiplicity of undulations due to a short period would carry no conviction whatever to my mind, but the manner in which the graph 'picks up' (in passing, so to speak) this isolated value of 1902 is most remarkable and, in my opinion, convincing Such a nine fold coincidence cannot be fortuitous

Abnormal Permeability Produced in a Steel Wire by Loading

USING the ballistic method previously described[1], recent investigations have shown that an abnormally high value for the permeability of a steel wire can be obtained by loading

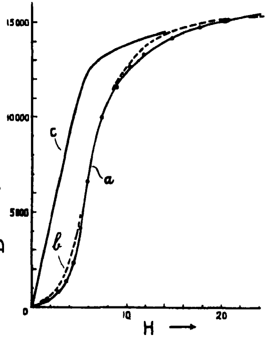

FIG 1

In Fig 1, the curve *a* shows the relationship of *B* and *H* obtained by the ordinary method of reversals for a mild steel wire of 0 092 in diameter, the wire being unloaded Curve *b* shows the values of *B* and *H*, also obtained by the method of reversals, when the wire was supporting a steady load of 202 lb (that is, a stress of 13 7 tons per sq inch)

By means of the ballistic test described[1], the increase of induction density ΔB was obtained as a function of *H* when a load of 202 lb was gently applied Before each application of the load, the magnetic intensity was raised to a value of about 200 gauss and the desired value of *H* was then reached by reversing the exciting current of the solenoid many times The curve *c* in Fig 1 has been obtained by adding the value ΔB to the corresponding value of *B* given by the curve *a* It is seen that for low values of *H*, the permeability given by curve *c* is more than ten times the normal value of the permeability as given by the curve *a*

Loading the wire when it is placed in a steady magnetic field of suitable intensity gives rise to a very marked increase of permeability

By means of a somewhat different procedure, Ewing[2] obtained very large increases of induction when an iron wire, which had previously been stretched beyond its elastic limit, was loaded For annealed iron wire, however, the effect was very much less So far as I am aware the results now given are the first yet recorded showing the immense increase of induction produced by loading an unfatigued steel wire

[2] *Phil Trans* 1885

A Haploid Plant of *Nicotiana sylvestris*

ATTEMPTS to produce a merogonic fully developed animal organism have been unsuccessful plants appear to be more convenient subjects for this purpose We know two androgenic haploids at the present time and both belong to the genus *Nicotiana* One was produced by pollinating a triploid *Nicotiana Tabacum* plant (2*n* 72) with *N Langsdorffii* (2*n* 18) From such a cross a *Nicotiana Langsdorffii* androgenic haploid with 9 somatic chromosomes was produced[1] The other androgenic haploid was produced by pollinating the amphidiploid *N glutinosa* × *N Tabacum* *N digluta* with *N Tabacum* (2*n* 48) From such a cross an androgenic *N Tabacum* with 24 somatic chromosomes has been produced[2]

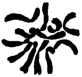

FIG 1 Somatic metaphase from a root tip of the haploid *Nicotiana sylvestris*

Recently we produced another *Nicotiana* haploid by pollinating the F_1 hybrid *N Tabacum* × *N sylvestris* with pollen from *N sylvestris* (2*n* – 24) Considering the former two cases, it seems very probable that the haploid thus produced has developed from a sperm nucleus The haploid is a dwarf *Nicotiana sylvestris* plant with smaller cells than the normal (diploid) *N sylvestris* The haploid has two chromosomes with small heads, two with large heads (subterminal constriction), four with medial constrictions and four with submedial constrictions (Fig 1) In the root tips of the haploid plant single cells or even whole sectors were found with diploid chromosomal constitution—a condition which often occurs in haploids

It is most probable that this haploid has developed from a *sylvestris* sperm nucleus, but it is also possible although not very probable that it has origin ated parthenogenetically from an egg cell having only *sylvestris* chromosomes Such an egg cell can be produced if all the *sylvestris* chromosomes (12) separate and move toward one pole while the *Tabacum* chromosomes (24) move toward the other pole during the reduction division in the F_1 hybrid The chance for such a chromosomal distribution during the reduction division is very small When we consider the fact that parthenogenesis is a rare occurrence—only one egg cell (haploid) may develop parthenogenetically out of several thousands—it seems very improbable that our *sylvestris* haploid has such an origin

Detailed morphological description of the haploid and its cytogenetical behaviour will be given elsewhere

Influence of Thyroid Preparations on the Plumage of Birds

IN an earlier communication[1] we described experiments on the supposed influence of the thyroid hormone on the moulting mechanism of feathers in aquatic birds which manifested very striking resistance to thyroid feeding and to the injection of thallium acetate After controlling the thyroid preparations which produced the shedding of feathers in hens and caused metamorphosis in tadpoles the thyroid glands of ducks and geese have been examined The great difference observed between them and the thyroid gland of the chicken was found to be due chiefly to different anatomical structure and to tremendous development of the corpuscula epibranchialia (corpuscula epithelialia or parathyreoidea of other authors) in ducks and geese

It seemed to us therefore that the corpuscula epibranchialia may have a neutralising effect on the influence of thyroid in our experimental aquatic birds It is also possible to presume such a neutralising influence in the testis hormone of drakes as suggested in the interesting publication of Mr R George Jaap of the University of Wisconsin in Poultry Science referring to testis enlargement and thyroid administration in ducks although we used in our experiment both male and female ducks

Bearing in mind this possibility we repeated the experiment now with a uniform batch (in regard to origin age and so on) of hens divided into four groups treated as follows (1) fed with thyroid preparations, (2) fed with thyroid preparations and given injections of extract (in Ringer s solution) of corpuscula epibranchialia of geese and ducks (3) fed with thyroid preparations and given injections of testis hormone prepared from drakes testes and (4) a control group given injections of Ringer s solution only and including other hens without special treatment

The result was again very striking While hens of the first and third groups began on the 8–9th day to lose their feathers and on the 12th day there were all the symptoms of severe moulting, the group injected with the extract of corpuscula epibranchialia as well as the control animals remained quite resistant to thyroid feeding

This experiment was repeated twice with the same result and at the same time histological examination was made of the corpuscula epibranchialia Some interesting results were observed, for example tadpoles given a very small dose of the extract of corpuscula taken from geese died on the second third day but the control tadpole fed on goose s thyroid gland and other thyroid preparations continued alive and active

A detailed report of these experiments is in preparation

Energy Spectrum of Positive Electrons ejected by Radioactive Nitrogen

THE velocities of positive electrons emitted by boron when bombarded by α particles of radium C with a range reduced to 6 3 cm were investigated by the magnetic focusing method, the electrons being detected by coincidences in two contiguous Geiger Muller counters[1] The measurements could only be extended up to the value of $H\rho$ 7800 The energy distribution obtained is shown in Fig 1 For each point of the curve 100–200 positive electrons were counted The natural background was 20 per cent of the measured value

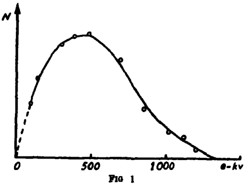

FIG 1

The shape of the curve is similar to that for the β spectrum of radium E The limit of the spectrum corresponds to about 1 3 × 10^6 ev A similar energy distribution was found by Anderson and Neddermeyer in the case of carbon bombarded by diplons[2] Thus the half period[3] and the energy spectrum of positive electrons of radioactive nitrogen do not depend on the method of its production

The most probable way of producing N^{13} in our experiments may be assumed to be

$$ {}_5B^{10} + {}_2He^4 \rightarrow {}_7N^{13} + {}_0n^1 $$

while in the case of Crane and Lauritsen, measured by Neddermeyer and Anderson the supposed reaction was

$$ {}_6C^{12} + {}_1D^2 \rightarrow {}_7N^{13} + {}_0n^1 $$

Thus, starting both from ${}_5B^{10}$ and from ${}_6C^{12}$ one gets the same kind of radioactive nitrogen ${}_7N^{13}$ with the same characteristic constants

The energy distribution in the case of aluminium and magnesium is similar to that of the β spectrum of thorium C + C″ the limit lying above 2 × 10⁶ ev

Absorption Spectrum of Diatomic Arsenic

A NEW system of some eighty absorption bands has been discovered in the spectrum of arsenic between 2200 A and 2750 A which can be definitely assigned to the diatomic molecule This includes the five faint fluorescence bands observed by Rosen[1] and tentatively ascribed to As_2 The whole system bears a striking resemblance to that of P_2 investigated by Herzberg[2] where $\Delta G''$ is about 750 cm^{-1} and $\Delta G'$ 470 cm^{-1} A preliminary analysis gives for arsenic ΔG values that are about 420 cm^{-1} for the lower and 270 cm^{-1} for the upper state The vibrational levels of both states converge very slowly

The emission spectrum of phosphorus is attributed by Herzberg to a ${}^1\Sigma_g^+ \leftarrow {}^1\Sigma_u^+$ transition in which the upper potential curve is crossed by another possessing a flat minimum and a lower heat of dissociation which is either a ${}^3\Sigma_u^+$ or a ${}^3\Pi_u$ state This causes predissociation in the upper and perturbation of the lower vibrational levels of the ${}^1\Sigma_u^+$ state The graph of the ΔG values of our arsenic bands shows a discontinuity at $v = 4$ which appears to represent perturbation similar to that observed by Herzberg

Bands of 'Heavy' Acetylene in the Near Infra-Red

THE infra red spectrum of acetylene prepared from calcium carbide and 93 per cent heavy water has been examined photographically up to 12 000 A with a 4 m absorbing length at 2 atmospheres[1] Four bands have been observed, all of which belong to C_2HD as indicated by the absence of alternating intensities In spite of the high concentration of the heavy water used no bands due to C_2D_2 have been observed in this region

So far, the fine structure of the strongest two bands (1·030 μ and 1 094 μ) has been measured The moment of inertia of C_2HD in its lowest state was found to be 27 90 × 10^{-40} gm cm^2 From the moment of inertia of ordinary C_2H_2 (23 50 × 10^{-40} gm cm^2) alone, it is impossible to get exact values for both the C–C and C–H distances It is now possible, however by combination of the moments of inertia of C_2H_2 and C_2HD to get an accurate value for both these distances without making any outside assumptions (Naturally the nuclear distances are supposed to be the same in both molecules) The result is $r_{CC} = 1\ 205$ A and $r_{CH} = 1\ 062$ A

As C_2HD is not symmetrical part of the selection rules valid for C_2H_2 no longer hold Therefore more transitions occur in C_2HD than in C_2H_2 This fact is illustrated by the accompanying table where preliminary values for the origins of the C_2HD bands are compared with the corresponding C_2H_2 bands The nomenclature of Mecke[2] is used with Lochte Holtgreven and Eastwood's[3] interpretation of the C_2H_2 bands The combinations $2\nu_a + \nu_1$ and $2\nu_a + \nu_2$ are forbidden for C_2H_2 according to Dennison's selection rules but not for C_2HD As will be seen the strongest band $3\nu_a$ is slightly shifted to *shorter* wave lengths in spite of the larger mass of one of the vibrating nuclei whereas the band $\nu_a + 2\nu_1$ is appreciably shifted to *longer* wave lengths It follows that $\nu_a \approx 3300$ cm^{-1} $\nu_1(s) \approx 2650$ cm^{-1} against 3277 and 3230 respectively in C_2H_2 This frequency shift is somewhat analogous to that observed by Wood[4] in the Raman spectrum of HDO

	C_2HD	C_2H_2
$3\nu_a$	9706 cm^{-1}	9641 cm^{-1}
$2\nu_a + \nu_1$	9139	—
$\nu_a + 2\nu_1$	8550	9835
$2\nu_a + \nu_2$	8410	

We are preparing to investigate HDO (H_2D, DCN and other heavy molecules in the same spectral region

De Causis Plantarum

IN a review of Dr Gunther's edition of Goodyer's Dioscorides in NATURE of February 17 reference is made to Goodyer's translations of Theophrastus, and the statement is made that so far as is known the manuscript translation in the library of Magdalen College prepared by Goodyer in 1622 23 is still the only English version of De Causis Plantarum' '

It may be of interest therefore to direct attention to the fact that the text of Book I of De Causis Plantarum with translation and commentary by Robert Ewing Dengler was presented in 1927 as a dissertation for the doctor's degree at the University of Pennsylvania and was published by the University among the theses for that year

Wooden Cauldron from Co Monaghan, Ireland A remarkable cauldron of wood has recently been acquired by the National Museum of Ireland It was found at Altartate near Clones Co Monaghan in 1933 at a depth of 160 cm in a peat bog 356 cm above the clay at the foot of the deposit The cauldron was undoubtedly complete when it was found but was broken by the finder and onlookers The remains have been restored by Prof J Bayley Butler and has been described by Dr A Mahr (*Proc Roy Irish Acad* 42 Sec C No 3) The dimensions are opening 34 cm × 35 cm external measurement 45 cm × 49 cm height 28 5 cm thickness 0 9 cm near rim to 2 cm The vessel is now slightly elliptical doubtless owing to warping The wood is poplar, the handle only one remaining of yew The cauldron is unique owing to the handles and the ornamentation on the upper portion The handle something between a triangle and a semi circle is a translation into wood of the ring handles of the well known riveted cauldrons of the late bronze age of Britain the ribbed lugs carved out of the solid wood also being reminiscent of the metal staples found in these cauldrons but the lugs of the Altartate vessel are on the shoulder the difference being due to the material The ornamentation consists of six concentric patterns with central dots encircling the upper portion The circles which are not closed are connected with each other by tangential bands these being a continuation of the bands forming the incomplete circles The concentric pattern is a faint reminiscence of the old metal rivets but has become purely ornamental Looked at as a whole the pattern has a step character like a debased spiral ornament No similar pattern is found in the Irish bronze age and it seems to be nothing but a clumsy expression of a provincial La Tène art The vessel may therefore be a belated descendant of metal cauldrons which had gone out among the well to do but lingered among the poorer classes The suggested date of early iron age is confirmed by a pollen analysis by Prof Knud Jessen

Diving Powers of Whales It is little likely that the physiological processes of the larger Cetacea will ever become known from direct observation For this reason Mr A H Laurie has felt that it would be well worth while to undertake a careful and detailed study of the properties of fresh carcases of the Southern Blue and Fin whales in the belief that he might thereby be enabled to make tentative but nevertheless useful deductions as to their mode of life The results of his observations and experiments (Discovery Reports 7 363 406 1933) provide striking confirmation of the soundness of this belief After analyses of the data which he has been able to collect Laurie supports the view—stoutly opposed by certain cetologists—that whales are capable of diving quickly to great depths and as rapidly returning again to the surface If this indeed be true (and the bulk of the evidence seems to point to this conclusion) certain physiological considerations of great interest are involved the most important of which is the whale s immunity from caisson sickness On the basis of human performance a whale which dives to a depth of 100 metres and stays down there for 15 minutes will require to spend rather more than 1½ hours in returning slowly to the surface in order to avoid this malady Yet all whalers are agreed that whales rise from deep soundings much more quickly than that Up to the present no convincing reason why whales enjoy immunity from caisson sickness has ever been put forward A very surprising yet exceedingly plausible explanation is now indicated by the results of Mr Laurie s observations and experiments He has found that whale blood both adult and foetal contains vast numbers of tiny bacteria like organisms provisionally referred to as X organisms These *X* organisms appear to possess the power of bringing about some kind of nitrogen fixation with the result that excess nitrogen dissolved in the blood under extra pressure does not escape from it on decompression and cause caisson sickness in the animal (see also NATURE 133 636 April 28 874 June 9 1934)

Adoption of an Orphaned Brood by a Wasp In the *Entomologist s Monthly Magazine* for April 1934 Mr G E J Nixon describes the finding of a rudimentary nest of *Vespa vulgaris* containing sixteen cells and of about the size of a golf ball The nest was dug out from the ground along with the queen and carried indoors The queen made no attempt to leave the nest until it was indoors and then it flew to a window The nest was suspended across the top of a fairly large and deep box and after several attempts to escape the queen was ultimately induced to adopt the new abode and was regularly fed At the time when the nest contained two cocoons and many larvæ of different sizes she disappeared and was not seen again Three days later a queen of the allied species *V germanica* was obtained, and this individual adopted the orphaned brood just as completely as if it were her own She accepted blow fly puparia and caterpillars which she malaxated and fed to the brood The experiment was brought to a conclusion owing to an accident which caused the comb to fall and become broken

Sex in the Myxomycetes A paper by S Abe in vol 1 of the Science Reports of the Tokyo Bunrika Daigaku (Tokyo University Koishikawa Tokyo) describes some very interesting experiments on male and female gametes of various slime fungi (On the Syngamy of some Myxomycetes pp 193–202 Jan 23 1934) The work deals with the planogametes of *Fuligo septica Ericonema aureum Didymium nigripes, Physarum crateriforme* and *Stemonites fusca* It was observed that one of the gametes (the male) moved towards the other and the two can be further differentiated by staining reactions Neutral red safranine neutral violet methylene blue and cresyl blue all stain male and female gametes differently The female gamete has a positive charge whilst the male is negative

Ice in the Arctic Seas. The survey for 1933 of ice in the Arctic Seas (*Isforholdene i de Arktiske Have*) by the Danish Meteorological Institute shows that unusually favourable conditions prevailed in the Barents and Greenland Seas where for the greater part of the year the ice was well to the north of the average limits Off Spitsbergen there was no ice to the west in winter and spring or from the middle of June through the summer and autumn The north coast was clear from May until August and the east coast was almost clear in August Novaya Zemlya was almost clear in July and entirely clear in August in which month Franz Josef Land was accessible in open water Not during the last 34 years have conditions been more favourable on the east coast of Greenland In March and April the edge of the pack was 120 miles west of its normal position and by August the whole coast between lat 70° N and Cape Farewell was clear of ice The coasts of Iceland were free throughout the year On the Newfoundland Banks ice was rare except in May Davis Strait was unusually clear in most months Hudson Strait was almost clear in August On the other hand conditions were severe in Bering Strait and the Beaufort Sea and towards Wrangel Island North of Asia so far as information goes the ice was abundant but it was mainly new ice The White Sea did not clear until May On the whole it would appear that the outflowing polar drift was checked in the Barents and Greenland Seas and diverted towards Alaska and eastern Siberia

Three Commercial Sands of Canada Several reports of the Canadian Department of Mines published early this year have reached us these appear to be mainly of interest to Canadians but one Investigations of Mineral Resources makes a somewhat wider appeal This pamphlet contains three papers all referring to certain sandstones the first is an account of a bed of Potsdam sandstone between Buckingham and Gatineau Point Quebec it appears to be a friable sandstone easily disintegrated into individual quartz grains which are rounded to subangular The authors (L H Cole and R K Carnochan) conclude that this deposit will probably yield a silica sand sufficiently free from iron for glass making The second paper by L H Cole refers to a band of Chazy sandstone at Hawkesbury Ontario The stone appears to be fine grained and strong is easily carved and worked and apparently would make a good building stone for which purpose it appears to have been used for something like a hundred years The third paper gives an account by S C Ells of the bituminous sands of McMurray Northern Alberta The author holds and has held for a considerable time that the McMurray deposit of bituminous sand should be regarded as a potential source of liquid hydro carbons The quantity of available bituminous sand appears to be very large it is assumed that its bitumen content is 12½ per cent and that the petroleum products derived from the bitumen would be about 75 per cent by volume of the bitumen The author estimates costs of production and shows that the material can be worked at a profit, and concludes that the conditions are favourable to commercial development of the Alberta bituminous sands '

Treatment of 'Slurries' in Coal Washing Every advance in technology creates new problems The need for cleaner coal led to development of coal washing But coal is friable and contains dust which interferes with the efficiency of most washing processes Therefore the dust may not be permitted to accumulate in the wash water, and tanks are provided where the dust is allowed to settle and form a slurry or mud of particles of coal and earthy matter Owing to the fineness and character of the dust particles the clarification of the wash water is often difficult and chemical precipitants are added to promote flocculation and deposition of the slurry This may contain more water than fuel and must be dewatered, after which it may be used as a low grade fuel or incorporated in the slack fed to coke ovens The dedusting of coal and the treatment of slurries form the subjects of Memoranda 13 and 14 of the Institution of Mining Engineers During coal strikes, accumulations of slurry have proved unsuspected fuel reserves of no small importance

Hot Wire Anemometers. The lecture on these instruments and their uses given at the Institut de Mécanique des Fluids of the University of Paris by Dr E G Richardson of Armstrong College Newcastle in March 1932 has been amplified by him and issued as an Institut pamphlet with the title Les Appareils à Fil Chaud (Paris Gauthier Villars) It extends to 68 pages and is well printed and illustrated After showing how the change of resistance of a wire carrying an electric current due to the movement past the wire of the gas or liquid in which it is placed may be used to determine the speed of the fluid he shows how by placing two wires parallel to each other and near together the sheltering action of one wire to the other allows the direction of the motion of the fluid to be determined The effects of to and fro movements of the fluid and of solid walls are also traced The second part gives an outline of the results obtained by these methods for the motions of the air about the wings of an aeroplane about a cylinder and in the pipes and cavities of musical wind instruments References to 62 papers dealing with the subject are given There are a few misprints Fig 2 p 16 and Camobell p 57 are examples

Atomic Weight of Cæsium The atomic weight of cæsium in use for some time rests on the work of Richards and Archibald and Richards and Françon who found the value 132 81 Aston and Bainbridge however found by the mass spectrograph that cæsium is a simple element and Aston s packing fraction together with the conversion factor from O^{16} to O 16 of 1 00022 leads to Cs 132 904 A redetermination of the atomic weight by chemical methods using cæsium from pollucite of Maine U S A made by G P Baxter and J S Thomas (*J Amer Chem Soc* May) has given a result in close agreement with that of Aston although sufficient reasons for the difference between their results and those of Richards and his collaborators are difficult to discover The cæsium salts were very carefully purified and showed no trace of rubidium or potassium on spectrographic examination The chloride was fused in a platinum boat in an atmosphere of nitrogen hydrogen, or various mixtures of hydrogen and hydrogen chloride before weighing The silver precipitation method with adjustment of the end point with a nephelometer, was used Fourteen experiments are reported the average ratio CsCl Ag being 1 56063 or Cs 132 903 By rejecting one experiment which gave rather low values the averages are CsCl Ag = 1 56065 and Cs = 132 906 The values for the first seven determinations for which probably the material was of slightly better quality are CsCl Ag 1 56070 and Cs = 132 911, the value finally adopted being Cs = 132 91 It is very reassuring that the chemical and physical methods have been found to agree so well in this region of the atomic weight scale, and that a supposed anomaly has been removed

Callender's New High-Voltage Research Laboratories

THE new high voltage research laboratories of Callender's Cable and Construction Co., Ltd., are being opened on June 22 by Lord Rutherford, before a distinguished company, which will include the Council of the Institution of Electrical Engineers, by special invitation of the president, Mr. P. V. Hunter. The laboratories occupy the buildings of the old Kensington and Notting Hill Gate Power Station, at 38 Wood Lane, W. 12. The large space and head room provided by these buildings have made them especially suitable for conversion to high voltage laboratories. Altogether, 30,000 sq. ft. of ground floor space have been equipped as research laboratories, together with associated stores and workshop. The laboratories have been organised and equipped in a manner which will enable research work to be carried out in any field associated with the transmission of electrical power.

The main high voltage equipment consists of two transformers by Ferranti, each for 500 kva. continuous output at 500,000 volts. It is believed that these are the largest transformers of this voltage available at present in the industry. The large size of the transformers has been made necessary by the large capacitance current which is required for cable testing at high voltage. These two transformers are situated in adjoining laboratories which are 130 ft. long, and 45 ft. and 28 ft. wide respectively. One of these transformers has been mounted on porcelain insulators, so that the tank of the transformer can be raised to a voltage of 500 kv. to earth. In addition, a large opening in the wall dividing the two laboratories enables the two transformers to be connected in parallel or in cascade, thus providing 1,000 kva. at either 1,000 kv. or 500 kv. The lay out of these two laboratories represents a distinct departure from the usual practice in high voltage laboratories. The two transformers have been located in the middle of the laboratories. Each transformer thus commands two testing areas, one on each side. In this way, it is possible for preparation work to be pressed forward in one area while the transformer is testing in the other area, with a complete absence of risk to the personnel concerned. It is a general experience in high voltage laboratories that the preparation time far outweighs the time spent in actual testing. It has been found, however, that the above arrangement of the transformers makes for efficient use of the testing equipment.

The question of supply to the transformers received very careful consideration. It was required that high voltage should be available at any frequency between 25 cycles and 75 cycles per second. At the same time, the very sharp response curve of the vibration galvanometer used in making dielectric loss angle measurements made it essential that, when testing at any given frequency, the alternator speed should be held absolutely constant with variation of load or with variation of such factors as the supply voltage. It was not found possible to obtain sufficiently constant speed regulation with the usual arrangement of a Ward Lennard set. The arrangement finally selected consists of a 3-phase synchronous motor, driving a 3,000 volt single phase alternator through a fluid gear box, which provides a continuously variable gear ratio over the above range. All this equipment is by Haslam and Newton, Ltd., of Derby. From the testing which has so far been carried out, it appears that this equipment is likely to prove entirely satisfactory.

The cable life testing laboratory contains transformer equipment by British Thomson Houston Co., Ltd., which enables long lengths of buried cable for 66 kv. and 132 kv. systems to be tested at twice working voltage under conditions which simulate service conditions. The two high voltage transformers are for 500 kva. and 1,000 kva. respectively. These transformers are supplied by 3,000 volt single phase alternators, direct coupled to 3 phase synchronous motors. In addition to the high voltage transformers, two loading current transformers supply a total of 1,500 amp., the high current windings being insulated from earth for 170 kv. This enables cable heating current to be superimposed on the cable conductor without interrupting the high voltage, and in this way the cables are passed through periodic heat cycles. An unusual feature of this transformer equipment is that double electrostatic screens have been provided between the primary and secondary windings for the purpose of enabling accurate dielectric loss angle measurements to be carried out on cables which are buried, and in which, therefore, the cable sheaths are necessarily earthed. The cables are buried in runs of about 200 yards in land adjoining the laboratories which consists of made up soil representative of normal London conditions.

In addition the laboratory possesses a large amount of smaller transformer equipment for voltages up to 120 kv. which is used for the development of cable accessories such as joints and sealing ends, and for general investigations into the theory and mechanism of breakdown of high voltage cable dielectric.

Smaller laboratories are provided for dielectrics, chemistry and physics, and these provide all facilities for a large number of investigations which arise out of the main research programmes on the high-voltage cables themselves.

Conversion of Municipal and Village Wastes into Humus

ALTHOUGH at the moment many agricultural regions are more concerned with the profitable marketing of their surplus produce than with methods designed to increase crop production, nevertheless there are important exceptions to this general rule. In India, for example, the food supply of the villages, some 500,000 in number, is markedly deficient in amount, while the low quality is considered by many medical authorities on the spot to be one of the chief factors responsible for the poor general health and want of resistance to disease on the part of the population. In other parts of the tropics the maintenance of the food supply of the people is always one of the major anxieties of the authorities. In such circumstances any practicable method, by which the local food crops can be improved and to some extent ensured will at once command attention Such a method has recently been worked out at the Institute of Plant Industry at Indore in Central India The earlier results were published by Messrs Howard and Wad in 1931 as The Waste Products of Agriculture which was reviewed in NATURE of November 21, 1931 In the February number of the *Indian Medical Gazette* of the present year Messrs Jackson and Wad have successfully applied the Indore method of manufacturing humus from agricultural wastes to the conversion of night soil and town refuse into a valuable compost*

During 1932 and 1933 town wastes have been converted into humus at three centres—(1) Indore City where the waste products of 60 000 inhabitants were dealt with, (2) the Indore Residency enclave with a population of 4 000, and (3) the lines of the Malwa Bhil Corps where the numbers are about 1 000 These three centres are representative of a large municipality a small town or military cantonment and an ordinary Indian village The arrangements for the conversion are very simple and inexpensive The humus factory consists of (1) a metalled service road 20 ft wide (2) a charging trench on either side 2 ft deep and 15 ft wide the floor and sides of which are preferably made smooth and impermeable so as to prevent the breeding of flies and (3) metalled storage areas at least 20 ft wide on which the ripe compost can be piled in heaps until it is sold The manufacture of compost which takes about a month consists in the proper arrangement and moistening of the raw materials—town and village refuse and night soil in the charging trench followed by the turning of the charge three times at suitable intervals An intense fermentation accompanied by a rapid rise in temperature to above 50° C at once sets in The copious aeration which is ensured by the proper admixture of the materials leads to the rapid oxidation of the organic matter and to the destruction of all noxious odours while the high temperature destroys the fly maggots and probably the ova of helminths and the spores of pathogenic bacteria as well

The chemical composition of the final product is very satisfactory The percentage of nitrogen on a dry basis is nearly 1 per cent while the percentages of phosphorus potash and lime are ample The results obtained with such crops as sugar cane wheat cotton lucerne and vegetables are such that the product finds a ready sale The sale proceeds are considerably greater than the cost of manufacture and therefore a substantial profit is obtained instead of the usual loss During the last year at Indore City for example a net profit of Rs 3 085 was obtained Under the old method of disposal at this centre the net deficit was Rs 4 535 From the point of view of sanitation and public health two of the medical officers in Central India—Colonels Tyrrell and Nicholson—record their opinion on the process Both consider that the method is likely to prove the most satisfactory system so far employed for the disposal of municipal wastes

The Indore results are already being taken up at other centres in India The process has been adopted by the Military Cantonment at Neemuch and at Okara a small town of 9 000 inhabitants in the Punjab At the suggestion of Sir Malcolm Hailey the Governor of the United Provinces the Public Health Department has decided to experiment with the method while the Public Works Department of New Delhi is examining the process with the view of applying it as a solution of their very serious refuse disposal problem

Measurement of Noise

IN a paper read to the Institution of Electrical Engineers on March 8 Messrs B G Churcher A J King and H Davies read a paper on experiments on the measurement of noise, with special reference to engineering noise problems (see also NATURE 132 350, Sept 2 1933)

The authors point out that the old conception that sounds can be classified into music and noise is untenable For their purposes they define noise as irksome or undesired sound For example, the sound of a radio set operated in a room to the pleasure of some of the occupants may constitute an irksome noise to others who wish to converse They discuss the laws governing the threshold of hearing the relation of the magnitudes of the stimuli at different frequencies which produce equal sensations of loudness and the relation between stimulus and sensation They define the threshold as the largest sound the complete removal of which is not detected

In determining the threshold, it is essential that there is no background noise The range of frequencies covered is 100–6,400 cycles per second at octave intervals so that measurements were made at seven frequencies Points determined in this way are sufficiently close to define the threshold curve

The experiments were carried out in the laboratories of Metropolitan Vickers Electrical Co Ltd Fifty persons were experimented on and were divided into male and female groups At 100 cycles per second the female group is 2 3 decibels less sensitive than the male At 800 cycles per sec there is a tendency in both groups for sensitivity to decrease with increasing age but the female group is now 2–3 decibels more sensitive than the male At 6 400 cycles per sec the average sensitivities of the two groups are approximately equal the three oldest males having a much lower sensitivity than the rest

The old loudness scale used by the authors and the decibel scale are logarithmic scales of physical stimulus Doubt is thrown on the correctness of this method of measuring sound sensation Experience has shown that the rate of increase of loudness with the decibels above the threshold is comparatively small at low intensities and much larger at high intensities Masking and balancing methods of measuring the noise were experimentally tried and the latter was found much the more satisfactory A pure tone was taken as the standard sound as it is easy to specify and reproduce accurately The procedure is to find the physical magnitude of the standard stimulus which produces a loudness sensation of the same magnitude as that due to the source under observation The judgment of loudness equality is much simpler than the estimate of the magnitude of loudness It was most important that the response of the telephones used should have a linear relation with the amplitude of the disturbance especially at high values of the amplitude

The authors have made measurements of the magnitudes of common noises on various scales In what follows, we give them in loudness units Calling zero the threshold of hearing, the ticking of a watch at three feet would be unity In a quiet saloon motor car it would be 10 Ordinary conversation at three feet would be 20, but if in a suburban steam train with the window open it would be 50 A loud motor horn at 100 feet was found to be 100 and two circular saws at three feet 160

The effect of placing the source inside a building is very pronounced An 800 cycle tone placed in an enclosure had a loudness of 41, whilst outside it was only 2 4 In making these measurements it is vitally important to take the background of noise into consideration It is a matter of everyday experience that one sound can drown another A list of typical noise levels is given For example, a busy main street in a certain city had a noise level of 22 When trains were passing it rose to 53 On a weekday on the ground floor of an office in the street with the windows open, the noise level was 22, but shutting the windows reduced it to 11 On a Sunday morning with the windows open it was 0 6 and closed 0 2 In a dining car in a train travelling at 60 miles per hour the level was about 50, but in a tunnel it rose to 82

When apparatus is installed near a main street in a busy city, we have to consider a background of between 20 and 50 In this case a comparatively loud noise is scarcely noticed On the other hand, when a residential hotel has to be considered, special precautions have to be taken The screening effect produced by adjacent buildings is sometimes of assistance At certain hours of the night the background may be so low as 1 unit and a much lower noise emission would have to be aimed at If the problem is to be adequately dealt with in quiet residential districts some form of enclosure must be used

Permeability Tuning in Radio Frequency Circuits

VARIABLE condensers are now so commonly employed in radio receivers to tune circuits including a constant inductance that the use, some years ago, of variable inductances or variometers with fixed condensers is apt to be forgotten For some purposes however the latter arrangement may have considerable advantages A paper by W J Polydoroff[1] refers to the advantages, particularly in the matter of selectivity, which result from tuning radio receiver circuits in such a manner that the ratio of the inductance to the resistance of the circuit remains constant These desirable results may be conveniently accomplished by a new type of ferro inductance The coil itself is designed to have the desired performance at the highest frequency in the band to be covered The effective inductance is then increased to tune to lower frequencies by introducing a magnetic core into the field of the coil As the core is inserted into the coil, more lines of the magnetic field are intercepted by the core, and in effect, the average permeability of the medium surrounding the coil increases from unity, for air, to a certain maximum when the coil is entirely encased in the core hence the term permeability tuning'

The successful application of this principle to radio frequency circuits depends upon the production of an iron core material having an appreciable permeability at the working frequency, but free from the property of introducing undesirable resistance into the circuit For many years, thinly laminated iron and stranded cores have been used for audio frequencies while compressed iron dust cores have also come into use for frequencies up to about 50 kilocycles per second Quite recently considerable attention has been paid to the use of both iron and high permeability alloys for the construction of these dust cores, in order to obtain the necessary high permeability without the accompaniment of serious losses at radio frequencies

In his paper, Polydoroff describes the use of pure iron reduced by hydrogen as a primary material for radio cores While hysteresis losses are apparently vanishingly small at radio frequencies, the eddy currents are proportional to the square of the frequency and to the length of the circular path around each minute particle The research described was directed at the broadcast frequency band, 550-1,500 kilocycles per second, and in this band the optimum grain size of the iron proved to be about 5 microns in diameter This iron powder is mixed with a suitable insulating varnish and compressed in heated moulds of the desired shape using pressures up to twenty five tons per square inch The resultant product has the appearance of solid iron, exhibits fair mechanical strength, and can be machined in the usual manner The effective permeability obtained in such materials varies from about 5 to 12 according to the pressure employed in the moulding process

The paper describes the use of this type of iron core in various types of radio receiver circuit A good quality single layer solenoid of small dimensions is used as the inductance, and the core is made of two parts, an outer cylindrical shell and an inner plug, so as to enclose the coil in the position of maximum inductance A semi fixed condenser is attached to the end of each coil, and this is initially adjusted to give resonance at the highest frequency required The cores are mounted on a common platform and inserted in their respective coils by a single tuning control Provision is made to move each coil or each core separately in order to produce synchronisation at the middle of the range

In receivers employing as many as six tuned circuits, no difficulty has been experienced in maintaining synchronism and constancy of the inductance to resistance ratio throughout the whole frequency band The arrangement is equally applicable to the supersonic heterodyne and the straight radio frequency amplifier types of receiver, and the advantages of the latter with the possibility of increased selectivity may give rise to interesting developments in the future

[1] Ferro-Inductors and Permeability Tuning , *Proc Inst Rad Eng*, May, 1933

University and Educational Intelligence

CAMBRIDGE —The title of Stokes lecturer in mathematics has been conferred on Dr M Born

Prof E A Owen professor of physics at University College Bangor of Trinity College has been approved for the degree of Sc D

The subject for the Sedgwick Prize for the year 1937 is The Application of Modern Technique to the Elucidation of Some Specific Geological Problem The prize is open to all graduates of the University and essays are to be sent in on October 1 1936

OXFORD —The question of the provision of sites in the University Park for the extension of the science departments which has lately given rise to much discussion has been settled by the adoption of certain decrees by Congregation By these it is provided that in addition to the area at present reserved a further area on the western frontage should be allotted for such extension when required while the remainder of the Park should be declared a public open space This arrangement has been approved without opposition though it would appear that if the requisite negotiations under the provisions of the Town and Country Planning Act 1932 are carried through the University will to some extent have forgone its freedom of action with respect to the portion not reserved for science

THE following International Lady Tata Memorial Scholarships each of the value of £400 for the academic year 1934 35 for research work in diseases of the blood with special reference to leukæmias have been awarded Dr W Bungeler (Danzig) Dr L Doljanski (Copenhagen) Dr M C G Israels (Manchester) Dr C Oberling (Paris) Dr J Engelbreth Holm (Copenhagen) Dr M O K Jørgensen (Aarhus Jutland) Dr R Meier (Leipzig) Dr Lucy Wills (London)

LEHRFREIHEIT manifestoes by organisations representing twenty two thousand American professors have been recently promulgated They are reviewed in a Press *communiqué* circulated on March 12 by the Institute of International Education of New York Specific reference to any foreign country is avoided but recent events in Germany are doubtless responsible for these declarations which do not ignore the fact that the United States itself is not immune from attacks upon academic freedom The following excerpts are typical American Association for the Advancement of Science— Our existing liberties have been won through ages of struggle and at enormous cost If these are lost or seriously impaired there can be no hope of continued progress in science of justice in government or international or domestic peace or even of lasting material well being Whether by governmental action, administrative coercion or extra legal violence we feel it our duty to denounce all such actions as intolerable forms of tyranny American Political Science Association— Every people has the right to live under the form of government it selects for itself It is not for outsiders to object because they do not like it But it is reasonable to deplore an action anywhere that may be absolutely destructive of gains in human progress that have been made only by great sacrifice Freedom of teaching is one such gain "

Science News a Century Ago

Sir Gilbert Blane, F R S

June 26 marks the centenary of the death of Sir Gilbert Blane F R S who with Robert Lind contributed more than anyone else to naval medicine and hygiene and the welfare of seamen He was born at Blanefield Argyllshire on August 26 1749 and received his medical education at Edinburgh under the celebrated William Cullen After obtaining his M D degree at Glasgow in 1778 he went to London became private physician to Sir George Rodney and accompanied him on a voyage to the West Indies On his return he submitted to the Board of Admiralty a memorial on the lack of cleanliness ventilation and dryness in ships the need for a supply of lemon juice for the prevention and treatment of scurvy the prevalence of drunkenness the inadequate care of the sick aboard ship the absence of proper bedding and soap and the need of a free supply of medicines and other necessaries to naval surgeons In 1782 he left Plymouth with Rodney and remained on active service until the end of the War with the American Colonies during which time he collected materials for his principal work entitled Observations on Diseases of Seamen" published in 1785 This book consisted of three parts devoted respectively to the health and diseases of the Fleet during the years 1780–83 the causes and prevention of diseases in fleets and the description and treatment of affections such as fevers dysentery and scurvy most frequently seen at sea During the last forty years of his life Blane was frequently consulted by the Government and others on various aspects of public health especially in connexion with the Navy

Babbage and Parliament

In his Passages from the Life of a Philosopher Babbage gives an entertaining account of the elections in which he took part On more than one occasion he was invited to become a candidate for Parliament and on June 27 1834 was nominated for Finsbury In proposing his name Mr F O Martin said that although Mr Babbage had never been in Parliament before that did not take from his utility He had however laboured to serve the public in other capacities and had the honour of being the successor in an office formerly filled by the illustrious Newton He was an advocate for the emancipation of the Jews and the removal of the disabilities affecting their Dissenting brethren

The candidature of Babbage was not regarded with favour in some quarters as there were three other candidates, and in the end his name appeared at the bottom of the poll with 379 votes while the two successful candidates secured 2 514 and 1 915 votes respectively In his Passages when recalling that he afterwards declined the honour of standing for Stroud he wrote I was not particularly desirous of wasting my time for the benefit of my country The constituency of Finsbury had already expressed their opinion that Mr Wakley and Mr Thomas Duncombe were fitter than myself to represent them in Parliament and in that decision I most cordially concurred

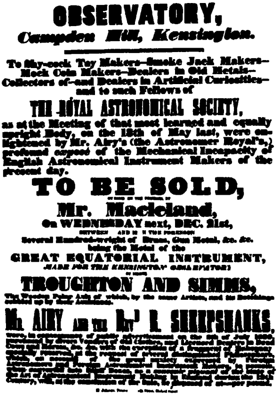
Travels of Lieut A Burnes

On June 28 1834 the *Athenæum* began a long review of the Travels into Bokhara of Lieut

Alexander Burnes with the remark that Since the days when we hung with rapture over the pages of Cook s voyages and felt ourselves inspired by some portion of the enthusiasm that animated the adventurous navigator we have met with no work by which we have been more interested delighted and instructed than the travels of Lieut Burnes Born at Montrose on May 16 1805 Burnes at the age of sixteen years entered the Indian army He became well acquainted with Oriental languages and soon gaining promotion, became an assistant political officer and was sent on various missions In 1832 at his own request he was sent on a twelve months expedition into Central Asia By his success in this expedition one writer said our traveller at once became famous He had retraced the greater part of the route of Alexander surveyed the kingdoms of Porus and Taxiles sailed on the Hydaspes crossed the Indian Caucasus, beheld the scenes of the inroads of Jengis and Timour and Baber but more than this he had detected a new pathway by which India might be invaded From this journey Burnes in 1833 returned home to receive the medals of the Geographical Societies of London and Paris and to be lionised by society Returning to India in 1835 he was employed by the Government on a mission to Afghanistan and six years later lost his life in the terrible massacre of November 1841

Sir James South s Telescope

Referring to the note in these columns under this title in NATURE of June 9 p 882 Messrs Sir Howard Grubb Parsons and Co inform us that they have a copy of the extraordinary poster which Sir James South used to advertise the sale of his great equatorial telescope The accompanying reproduction is from a photograph of the poster



OBSERVATORY,
Campden Hill, Kensington.

To Sky-cock Toy Makers—Smoke Jack Makers—
Mock Coin Makers—Dealers in Old Metals—
Collectors of—and Dealers in Artificial Curiosities—
and to such Fellows of
THE ROYAL ASTRONOMICAL SOCIETY,
as at the Meeting of that most learned and equally upright Body, on the 13th of May last, were enlightened by Mr. Airy's (the Astronomer Royal's,) profound *exposé* of the Mechanical Incapacity of English Astronomical Instrument Makers of the present day.

TO BE SOLD,
Mr. Macleland,
On WEDNESDAY next, DEC. 21st,
Several Hundred-weight of Brass, Gun Metal, &c. &c.
being the Metal of the
GREAT EQUATORIAL INSTRUMENT,
MADE FOR THE KENSINGTON OBSERVATORY
TROUGHTON AND SIMMS,

International Co operation in Science

AT the present time when all nations are faced with many difficult problems in economics as well as in their political relations with one another, they are being compelled to organise their resources to the best advantage and this may lead and in certain cases has led to preferring a nationalised system to the international co operation that many would rather aim at This influence must also be felt by scientific men and may tend to make them visualise the problems with which they deal from a more restricted point of view

On the other hand science itself has been advancing at an ever increasing pace during recent years and this has been largely due to the free and active international co operation which has existed and to the personal relationships which have been formed between scientific men in all countries Not only has this been the case in the exact sciences and in their various applications to the welfare of the community but also it is being widely held that investigations carried out on scientific lines will greatly aid in the solution of many of the problems of the present time Science, which is much more than the mere systematisation of data has done so much to promote international co operation in its own field that it may well encourage a similar spirit in other fields of human activity

International co operation in science it may be granted is generally accepted by scientific workers but it is by no means certain that the fact is equally appreciated by those who are politically in control of world affairs The question must often have arisen therefore whether or not a clear and formal declaration should be made by a responsible body of the principles of co operation between men of all nations which have proved so fruitful for the progress of science

Clearly such a declaration would have to come from a body as widely representative as possible of scientific thought There is not at the present time any scientific organisation which includes all nations of the world, but to the International Council of Scientific Unions which is meeting next month at Brussels some forty countries have already adhered and others can join it at their own desire Moreover the Unions related to it work through about a hundred and thirty national committees in the various countries, which have adhered to one or more of these

Unions in order to promote international co-operation in their particular fields of science

Here then is a large and active international organisation which might with advantage discuss at its forthcoming meeting this problem of international co-operation on wider lines, and in fact the Royal Academy of Sciences in Holland has notified its wish as a member of the International Council to bring this question to the notice of the General Assembly A resolution has been circulated to the countries and the Unions which are members of the Council in which, after expressing the conviction that ultimately a way will be found leading to a more harmonious structure of the world, stress is laid upon the importance of maintaining international co operation in the domain of science in all circumstances While realising that in every country scientific men will be drawn more and more into spheres of national organisation the resolution expresses the hope that they will not lose sight of the international character of science, and will continue to foster the conditions necessary for international co operation since the 'brotherhood' of men of science can be an important factor in attaining the mutual understanding and helpfulness so necessary not only for science but also for all aspects of human endeavour

The International Council cannot dictate a policy to the various Unions, but there is little doubt that the adoption of a resolution on these lines would carry considerable weight Moreover, although the resolution is directed to allied organisations, it is clear from its tone and general content that it is meant to be an appeal to all scientific organisations, and to all scientific workers as well, urging them never to lose faith in the significance of science, pure and applied, for mankind It is to be hoped that the appeal will find a response in every country, whether adhering to the International Council or not, for it is a matter which stands above all political and other divisions The International Council, as the largest existing body representative of international science, is the appropriate body to issue such a declaration, and we trust that it will be given careful consideration If the immediate effect alone would be to induce those countries which are not yet represented upon the International Council to find an opportunity to join in its work, then the resolution might be regarded as a significant step towards the establishment of fuller co-operation among the scientific workers of the world

The Description of Nature

Atomic Theory and the Description of Nature 1 *Four Essays, with an Introductory Survey* By Niels Bohr Pp vi+119 (Cambridge At the University Press, 1934) 6*s* net

It is fitting that the year in which the Bohr theory comes of age should hear a pronouncement by its author on the view of Nature to which it has led It is true that in one sense the pronouncement is not up to date (the book is a reprint of previously published articles, the latest of which first appeared in 1929), but the scant amount of fundamental progress in the last few years, combined with Bohr's remarkable power of always seeing a little ahead of the existing position, makes this of small significance The most striking of the subsequent advances have been the discoveries of the neutron and the positive 'electron , and in the other volume containing a number of later essays on the same subject, in which the general point of view is further developed", which we are promised in the foreword we may hope to find some account of the theoretical aspect of these discoveries In the meantime however, the present volume may be taken as a true representation of the view of Nature afforded by the quantum theory to one of the keenest pairs of eyes in the world of physics

Two of the four essays which, together with an introductory survey, make up the contents of the book are familiar to readers of NATURE, having been published as Supplements in 1925 and 1927 The third essay appeared in German in *Die Naturwissenschaften* in 1929, and the fourth in Danish in *Fysisk Tidsskrift* in the same year The introductory survey also appeared originally in Danish in the Year Book of the University of Copenhagen for 1929 Although, therefore, only a portion (a little less than half) of the material now makes its first direct appeal to English speaking readers, that portion is the latest and, as it happens, the most concerned with the broader aspects of the subject

Bohr's view of the situation created by the quantum theory is well known, and his principle of 'complementarity' is perhaps the clearest expression yet given to the dilemma by which we are faced

"The definition of the state of a physical system, as ordinarily understood, claims the elimination of all external disturbances But in that case, according to the quantum postulate, any observation will be impossible, and, above all, the concepts of

> space and time lose their immediate sense. On the other hand, if in order to make observation possible we permit certain interactions with suitable agencies of measurement, not belonging to the system, an unambiguous definition of the state of the system is naturally no longer possible, and there can be no question of causality in the ordinary sense of the word. The very nature of the quantum theory thus forces us to regard the space-time co-ordination and the claim of causality, the union of which characterises the classical theories, as complementary but exclusive features of the description, symbolising the idealisation of observation and definition respectively."

It thus appears that the classical theories were aiming at a description of Nature which it is impossible to realise, and whenever we have to deal with phenomena in which the quantum of action becomes significant, we must renounce either the concept of space-time or the principle of causality. This does not mean, however, that the essence of Nature as represented by the statement of natural laws is to be regarded as dual. "There can be no question of a quite independent application of the ideas of space and time and of causality. The two views ... are rather to be considered as different attempts at an interpretation of experimental evidence in which the limitation of the classical concepts is expressed in complementary ways."

In such a situation our natural impulse—justified, if justification is necessary, by the success of the special theory of relativity—is to reformulate our ideals so as to make the impossible a thing of no meaning. Just as we escape from the obscurantism of the Michelson-Morley experiment by, fox-like, regarding the grapes of absolute velocity as sour, so we might seek for a point of view from which the concept of space-time or the principle of causality loses all significance. Bohr, however, will not attempt to meet the difficulty in this way. He insists that there can be no escape from a space-time description of experience, space-time being apparently in his view a necessary mode of perception.

> "According to the view of the author, it would be a misconception to believe that the difficulties of the atomic theory may be evaded by eventually replacing the concepts of classical physics by new conceptual forms. Indeed ... the recognition of the limitation of our forms of perception by no means implies that we can dispense with our customary ideas or their direct verbal expressions when reducing our sense impressions to order. No more is it likely that the fundamental concepts of the classical theories will ever become superfluous for the description of physical experience." And again: "It lies in the nature of physical observation, nevertheless, that all experience must ultimately be expressed in terms of classical concepts, neglecting the quantum of action."

With this as a guiding principle there is clearly nothing to do but to accept defeat, and Bohr, who is the incarnation of logic, capitulates unreservedly. "A conscious resignation," he says, is implied in the original quantum postulate, and "we must ... be prepared to find that further advance ... will require a still more extensive renunciation of features which we are accustomed to demand of the space-time mode of description."

It may be a futile rebellion against implacable Fate, but we must confess an unwillingness to submit to this depredation of our philosophical rights. Nor does such an attitude seem entirely Promethean. True, there is no evading the choice which the principle of complementarity imposes on us, but we fail to see that in discarding the possibility of a complete space-time description of Nature we weaken in the least our chance of fulfilling the traditional task of science which, in Bohr's accurate and succinct phrase, "is both to extend the range of our experience and to reduce it to order". We cannot accept the view that the interpretation of experience rests ultimately on the space-time concept. Interpretation is a logical process, and the laws of logic are independent of the concepts which they relate together. If the space-time concept has qualities which unfit it for relating the facts of experience, we must discard it in favour of something more suitable. There is nothing inherently impossible in this: it is simply a matter of cultivating our power of abstraction and expelling deeply rooted prejudices. That space-time is by no means necessary to logical thought is sufficiently evident in the fact that we can reason about such non-spatio-temporal ideas as courage, virtue, desire and a score of others; and although these particular concepts (and, we may add, that of free will) are obviously unsuited to physical applications, their existence justifies belief in the possibility of suitable ones until proof to the contrary is forthcoming. "Il faut vivre," pleaded the Abbé Desfontaines. "Je n'en vois pas la nécessité," replied the Comte d'Argenson. Only the former, we believe, was committed to a renunciation.

To be somewhat more specific, let us consider what is actually involved in the fact that the state of an observed system is altered in an unknown way by the agencies of observation There is an indeterminacy here only if we persist in analysing the observation into a thing observed and a means of observation As Bohr points out, the details of the analysis are arbitrary (we can include part of the observing apparatus in the system if we like), but what is much more vital is the fact that, so far as the ordering of our observations is concerned, the analysis itself is voluntary What we are given in experience is simply an observation—represented by a number Its expression as a relation between an object and a perceiving subject has been (and still is for large scale phenomena) an exceedingly useful one, but no more inevitable than the analysis of motion into an inertial and a disturbed part If we so express it then it is indeed difficult to see how we can make the hypothetical object independent of space and time, and we are forced to submit to the ambiguities of the quantum theory , but this very fact is surely an argument for discarding the analysis

By this simplification we avoid the dilemma so clearly expressed by Bohr in the following passage For describing our mental activity we require, on one hand, an objectively given content to be placed in opposition to a perceiving subject while, on the other hand, as is already implied in such an assertion, no sharp separation between object and subject can be maintained, since the perceiving subject also belongs to our mental content ' A sharp separation however can be maintained—in physics at least the object is experience (or observations) , the subject, reason Reason is never an object of study in physics whatever psychology may do with it, and no overlapping is therefore possible Confusion arises only when we *sub* divide the object, experience into a thing observed and a means of observation, for the quantum theory teaches us that no unambiguous subdivision of this kind can be made To avoid confusion, therefore, we have simply to accept experience as it is

On a very interesting page Bohr discusses an unusual aspect of the space time concept

> One need only remember here the sensation often cited by psychologists, which every one has experienced when attempting to orient himself in a dark room by feeling with a stick When the stick is held loosely, it appears to the sense of touch to be an object When, however, it is held firmly, we lose the sensation that it is a foreign body, and the impression of touch becomes immediately localised at the point where the stick is touching the body under investigation It would scarcely be an exaggeration to maintain, purely from psychological experiences, that the concepts of space and time by their very nature acquire a meaning only because of the possibility of neglecting the interaction with the means of measurement "

It is instructive to consider this passage in connexion with the doctrine that the space time concept is inevitable for the description of Nature If we could make assertions about space and time 'purely from psychological experiences', it is clear that we should have to grant them a sort of inevitability, as Bohr maintains, but a question concerning the use of words arises here The experience described seems to us no more psychological than that of any physical experiment , it is simply derived from a different physical sense—the sense of touch instead of the customary sense of sight The problem which suggests itself (an interesting one) is whether the voluntarily adopted concepts of space and time (so far as they are applicable at all) need to be endowed with the same properties to enable them to correlate tactual as to enable them to correlate visual sensations Physics, however, relies very little on the sense of touch, and the question is therefore of philosophical rather than of practical interest

If, however, we feel that Bohr presents us with a clear statement of a problem rather than its solution—with an appetite rather than a meal—we must not neglect to point out that the renunciation to which we object is accepted by him not merely with fortitude but with enthusiasm We must consider this very renunciation " he says, "as an essential advance in our understanding " 'My purpose has been to give expression to our enthusiasm for the prospects which have been opened up for the whole of science ' This is an attitude possible only to a fearless mind and a noble spirit it is one which we respect and admire, but cannot share HERBERT DINGLE

Mechanised Medicine

Red Medicine Socialized Health in Soviet Russia By Sir Arthur Newsholme and Dr John Adams Kingsbury Pp xi+324+18 plates (London William Heinemann (Medical Books), Ltd , 1934) 10*s* 6*d* net

THIS work is an examination of the conditions of medical practice in Soviet Russia in 1932 Its entertainment value is indubitable and is derived from the description of a five weeks' tour made in the summer of 1932 during which the distinguished authors travelled more than six thousand miles of Soviet Russia They write with a boyish enthusiasm and *naïveté* which gives the book great charm They recognise that in an implacably 'conducted' tour they were shown the best and not the worst

The scientific value of such a tour is, of course, slight Seven days of the short period were spent on steamships on the Volga and Black Sea, and much of the rest of the time in railway travel The real value of the book rests upon the fact that the authors are authorities on their subject and apart from their brief visit, they have steeped themselves in the literature of Russian medicine In fact, the work is to be considered as the coping stone to a considerable series of studies on the relation of private and official practice of medicine carried out in eighteen countries and published in three volumes by the American Milbank Memorial Fund in 1931

As the result of these studies, the authors became convinced medical (though not necessarily political) communists Private medical practice, as carried out in western countries is to them anathema and they passionately desire the cessation of remuneration to the doctor for each medical act They would have all practitioners State servants This being so, the organisation of medical practice in Soviet Russia is naturally much to their liking, and their descriptions of it are frequently the occasion of the shaking of a minatory fist or, at any rate, the wagging of a hortatory finger at the medical customs of the west To emphasise this, the authors, while writing in an enthusiastic manner of all they approve in Russia, studiously avoid discussion of many things of which they clearly disapprove, as this would weaken the effect they wish to produce

In a chapter on public abortion, we learn that any pregnant multiparous woman in Russia can demand, as a right, entry to an institution in which abortion is induced by State doctors, and we are informed that in Moscow in 1929 total abortions were sixty-one per cent in excess of normal births There are chapters on the care of maternity, the care of children and youths and the care of the workers, but in vain does one look for a chapter on the care of the aged, to this no reference is made Amongst the photographs with which the book is lavishly adorned, a picture of a works committee discussing production produces astonishment This is no witenagemot, for the committee consists of young persons scarcely more than children Later, figures are given from which it may be deduced that the average age of a Russian of to-day is about twenty years

The fact appears to be that war, pestilence famine and pogrom have done their work very well In the language of the book, old age has been liquidated' and in Russia we are faced with a population which consists literally, and not merely metaphorically, in children This fundamental fact being ascertained, does it not throw a great illumination on all that is happening in the land? The vital statistics which crowd this book need correction for age distribution and cannot be applied crudely for comparison either with western States or with Tsarist Russia

The authors are amazed at the extent of the provision for the sanatorium treatment of tuberculosis which has been procured by the conversion of nobles' palaces They do not appear to have been struck with amazement by the need for all this provision From figures given, it is clear that there is a tuberculous problem in Soviet Russia of great magnitude The case rate for tubercle per 10,000 of the population is 116 5 and appears to be on the increase In London it is 16 65 It is not necessary to look far to explain this high incidence Rapid industrialisation, bad housing, insufficient food supply, and a juvenile population, contain all the necessary ingredients for the production of an alarmingly high incidence

Although State curative medicine is organised on a vast scale, there is grave doubt not only whether there are sufficient doctors, but also of the efficiency and training of those that exist In this, as in many other respects, quality has been sacrificed to quantity

Of preventive medicine there is little said, which is rather surprising since Sir Arthur Newsholme may be regarded as the Nestor of English sanitarians, but, no doubt, the reasons are first that the matter under consideration is not preventive but curative medicine, and secondly that there is as yet little sanitation to be observed in Russia It is pointed out, however, that the high and continuing incidence of typhoid fever, typhus and dysentery throw a strong light upon the neglect of domestic cleanliness and communal sanitation

The authors deplore the absence of domiciliary medical treatment, but the word "home" contains a bourgeois idea and where there is no *domus* there can be nothing domiciliary

At the conclusion, the authors do allow

themselves one misgiving and this is Can such an order (that is a better social order) in the fullest sense be created which does not include recognition of man s spiritual relation to the divine ? This of course is also a shockingly bourgeois sentiment

Scientifically the case must be judged on biological grounds Soviet Russia is a vast biological experiment Unfortunately our biologists are hopelessly at variance on the very point which would put all doubts at rest and the question is still an open one If Prof MacBride is right the communist governors of Russia are right and we may order our tumbrils If Weismann is right they are wrong and we may sleep quietly in our beds

Aluminium and Tungsten

Gmelins Handbuch der anorganischen Chemie Achte Auflage Herausgegeben von der Deutschen Chemischen Gesellschaft (1) *System Nummer 35 Aluminium* Teil B Lief 1 Pp 308 48 gold marks (2) *System Nummer 54 Wolfram* Pp xviii+xi+397 64 gold marks (Berlin Verlag Chemie G m b H 1933)

(1) THIS section of Gmelin s Handbuch which has appeared before the publication of Part A deals with the compounds which aluminium forms with the principal non metals (except silicon and phosphorus) No stable hydride of aluminium is yet known the only evidence of its formation being derived from band spectra produced in various ways but R S Richardson has detected it in the sun s envelope

A large part of the volume is devoted to alumina Methods of preparing well formed crystals of the oxide and a list of patent specifications relating to the manufacture of large single crystals which are used as synthetic gems are detailed The two main technical processes used in the purification of alumina from bauxite are given in convenient schematic form Hitherto all attempts to extract alumina from bauxite by means of caustic soda at atmospheric pressure have been unsuccessful One of the most notable achievements in the technology of aluminium is the separation of sodium aluminate into its constituents by mechanical agitation The history of this idea is traced to an observation by Bonsdorff in 1833 In 1859 Le Chatelier suggested the crystallisation of alumina from hot supersaturated solutions but no practical result was attained until 1887 when K J Bayer patented the modern process

In the present process the alkaline liquor is first seeded with crystals of alumina and then mechanically stirred No completely satisfactory explanation of the process has been devised Neither sand glass powder graphite nor colloidal alumina can be substituted for the crystals used for seeding and even crystalline alumina itself is often ineffective The best material for the purpose is the product which crystallises out between 25° and 35 C and a somewhat narrow range of concentrations is also desirable

The preparation of alumina from other compounds is also dealt with very fully and the hydroxide is described under the headings of gels sols and crystals There is a long list of references to the literature on the manufacture of aluminium nitride which is used in the Serpek process for synthesising ammonia Aluminium chloride is also fully described but its use in organic chemistry falls outside the scope of the work

Several organic derivatives are recorded for example aluminium carbide and various salts but not aluminium trimethyl The organic salts of aluminium have attracted less attention than those of many other metals but the acetate is important both in analytical work and in the dyeing industry The records of its stability in hot solutions are somewhat contradictory but the formation of colloidal alumina when a solution of the acetate is boiled appears to have been observed by Gay Lussac in 1810 Aluminium formate acetate and tartrate all give evidence of complex ion formation Thus normal reactions of the metallic ion are suppressed Biot observed so long ago as 1835 that concentrated aqueous solutions of the tartrate were lævorotatory but the pure salt has not yet been isolated with certainty The chemical nature of all these organic salts seems to call for further investigation

(2) The importance of tungsten in modern industry has led to the accumulation of a vast amount of information about the properties and uses of this metal The first reference to it seems to have been made by Ercker in 1574 but until the end of the eighteenth century the word wolfram (with a great variety of spellings) was used to denote the ores of tungsten which are often associated with tin and interfere with the extraction of that metal Scheele first separated the acid oxide in pure form and recognised it as something different from molybdic acid whilst the Spanish brothers de Lhuyart first isolated the metal in 1783 Exact quantitative work on the

lower oxides was undertaken by Berzelius in 1816 but the industrial application of tungsten was delayed until 1847 although an alloy with iron had long been known After the Paris Exhibition in 1900 the use of tungsten in steel manufacture became general and three years later filaments of the metal were used in electric bulbs

Very interesting data are given relating to the production of tungsten Before 1910 Australia was the largest producer in the world then Burma and the United States gained the lead for a few years but since 1918 the greater part of the world s output has come from China In technical research Germany led the way until her supplies were cut off during the War

Tungsten is used as a hardening component of certain alloys and also as a pure metal Carbide of tungsten is an important constituent of the hard alloys and tabulated lists of references to the patent specifications are grouped according to the melting or sintering properties of the alloys Recent industrial applications of the pure metal have been largely due to its low volatility and high melting point It has practically replaced all other metals as lamp filaments and it is used for making electrodes thermo elements and many other appliances This volume is packed with details about the properties of tungsten and its compounds and the literature has been revised to April 1933

Modern Geometry

Analytical Geometry of Three Dimensions By Prof D M Y Sommerville Pp xvi+416 (Cambridge At the University Press 1934) 18s net

THIS is a textbook it is not too difficult for the average honours student it includes the material usually required for examinations yet it also includes less usual subjects such as line geometry cubic and quartic curves cubic surfaces ruled surfaces higher space the Veronese surface the application of matrices invariants and invariant factors above all it conveys something of the true spirit of modern geometry For many years geometrical research has been made both easier and more effective by projective methods and space of more than three dimensions but this had not hitherto found recognition in any sufficiently elementary English textbook

Though primarily algebraical and three-dimensional the book provides a more unified knowledge of geometry by the frequent use of purely geometrical methods and by excursions into one two four and five dimensions It does not deal with birational transformations or topology Its reasoning is in general particularly concise and intelligible though occasionally condensation renders the argument obscure A carefully chosen first course of reading makes it really suitable for those whose knowledge of co ordinate geometry is limited to elementary conics References to more detailed expositions are too scanty

The treatment of the straight line plane and quadric accords with examination requirements but rectangular Cartesians are systematically supplemented by homogeneous co ordinates line co ordinates matrices and (most conspicuously and successfully) the circle at infinity and other projective methods There are useful notes on imaginary elements Beginners may possibly find the projective investigation as an introduction to focal properties somewhat overwhelming The invariants of two quadrics are treated extensively Segre characteristics are sufficiently explained Certain chapters would benefit from a more comprehensive selection of heuristic examples

Elsewhere pure projective geometry tends to predominate In one chapter co ordinates are established without reference to metrical considerations difficulties are avoided by assuming openly the fundamental theorem

The curve theory includes developables the (plane) Plucker relations Luroth s theorem the twisted cubic and its polar system twisted quartics of both species curves upon a quadric A chapter on line geometry deals with the quadric in five dimensions The treatment of surfaces includes curvature polar surfaces the effect of isolated singularities on class ruled surfaces double curves the cubic surface and its twenty seven lines the Steiner surface the Veronese surface normal varieties the cyclide

Misprints are not serious (y) for (x) on p 371, is slightly confusing A few statements require emendation three concurrent lines on a cubic surface do not necessarily meet in a node quartic surfaces are known containing as many as sixty four lines despite Continental nomenclature the general point of a double curve should not be confused with a binode part of 14 683 is incomprehensible Terms are too freely used in an unconventional sense without warning for example linear series (for regulus) self conjugate tetrahedron

The excellence of this work emphasises how much geometry loses by the recent death of its author

Short Reviews

The Physics of Electron Tubes By Dr L R Koller (International Series in Physics) Pp xiii+205 (New York and London McGraw Hill Book Co Inc, 1934) 18s net

ONE of the most useful functions of books or monographs on limited and somewhat specialised branches of scientific knowledge is the summary in a convenient and critical form of all the available information on the subject This function is admirably fulfilled in Dr Koller's monograph which, in the space of some sixty thousand words presents a survey of electron emission and its application to the various types of valves and photoelectric cells in use to day

Beginning with the general theory of thermionics the characteristics of the emission from various types of cathode are described together with practical advice on the construction of such cathodes and their use in electron tubes The deleterious action of gases and the methods for securing their removal are dealt with for the high vacuum type of valve while two chapters are devoted to the gaseous discharge tube the technical applications of which have been so widely developed in recent years In a similar category may be placed the photoelectric cell, the fundamental physics of which are adequately covered The whole book has the merit of not being overloaded with matter which is now more of historical than of fundamental scientific interest In spite of this, however the work gives a sense of completeness in reviewing the whole subject, and the tables of data and lists of references given at the end of each chapter will prove invaluable to the reader whose scientific or practical interest in the subject would necessitate his delving much deeper than is possible within the limits of a single volume The general sense of this notice is thus thoroughly to recommend the book as a scientific and practical introduction to the subject covered by its title The production of the book is excellent

The Annual Register a Review of Public Events at Home and Abroad for the Year 1933 Edited by Dr M Epstein Pp xii+312+184 (London, New York and Toronto Longmans Green and Co, Ltd, 1934) 30s net

THE full summary of the past year's history again appears in this indispensable work of reference Great Britain and the Empire naturally receive most attention and there are full accounts of the efforts in the cause of disarmament, and the hopes of the World Economic Conference Then follow sections on the League of Nations and foreign history, with ample attention to events in Germany and the crisis in the United States The second part of the volume as usual contains a chronicle of events, the year's obituary with admirable short biographies, and retrospects of literature, art, drama, science law and finance Little of importance can be overlooked in these packed reviews of various branches of achievement Science is dealt with in thirteen pages and is a useful record of the year's discoveries and publications A full index completes the volume

Adam's Ancestors an Up to-date Outline of what is known about the Origin of Man By Dr L S B Leakey Pp xix+244+12 plates (London Methuen and Co, Ltd, 1934) 7s 6d net

IT is no detraction from the merits of Dr Leakey's book to say that it does not call for extended notice The alternative would be to devote to controversial matters as much space as the author himself has given to their discussion For his book is not merely an introductory study for the use of the layman—a purpose which it serves admirably—but it has also afforded the author the opportunity of laying before his fellow specialists his views on obscure and controversial matters—such questions for example, as the dating and sequence of Mr Reid Moir's pre palæolithic cultures in East Anglia the relation of the various cultures now distinguished in the early phases of the Old Stone Age, the classification of the deposits of late Tertiary or early Quaternary times and so forth Dr Leakey's views are stated clearly and with due restraint

Handbuch der anorganischen Chemie In 4 Banden Herausgegeben von Prof Dr R Abegg, Dr Fr Auerbach und Dr I Koppel Band 4 *Die Elemente der achten Gruppe des periodischen Systems* Teil 3 *Kobalt und seine Verbindungen* Lief 1 Herausgegeben von Dr I Koppel Pp xvi+626 (Leipzig S Hirzel 1934) 58 gold marks

THIS instalment of Abegg's 'Handbuch" includes sections on the atomic weight of cobalt, the cobalt atom, cobalt metal, cobaltous and cobaltic compounds alloys and compounds of cobalt with metals and metalloids, cobalt ammines, and a final short section on the colloid chemistry of cobalt and its compounds It provides a monumental record of the properties of a very interesting element at a price which makes it more suitable for libraries than for individual purchasers

Aids to Botany By H J Bonham (Students' Aid Series) Pp viii+221 (London Baillière, Tindall and Cox, 1934) 3s 6d

THIS book sets out to provide a revision course in botany for Higher School Certificate candidates and first year university students reading for the intermediate science or pre-medical examinations in the subject The scope of the book, however, is scarcely that of present-day requirements, and in a second edition many of the diagrams should be improved

Tidal Estuaries Forecasting by Model Experiments*

By PROF A H GIBSON

THE earliest work on tidal models was carried out by Osborne Reynolds at the University of Manchester in 1885 on scale models of the Mersey estuary This was followed by an investigation into the general question of the use of such models in which Reynolds co operated with a committee appointed for this purpose by the British Association in 1888 The experiments were devoted mainly to an examination of the behaviour of models of the same hypothetical estuary of symmetrical shape to different scales As a result of this investigation the committee reported in 1891 to the effect that It would seem therefore that by carefully observing certain [stated] pre cautions the method of model investigation may now be applied with confidence to practical problems

Shortly afterwards Vernon Harcourt carried out an investigation on a model of the estuary of the Seine in which the results of improvements made in the estuary since about 1833 are stated to have been reproduced with considerable accuracy Between 1890 and 1926 very few investigations of this kind appear to have been carried out and these for various reasons not with any marked degree of success

Any scale model in which fluid motions are involved must not only be geometrically similar to its original but also the velocities must be so related to corresponding velocities in the original that all corresponding forces are in the same ratio The model and its original are then dynamically similar and all lines of flow and wave formation will be similar The speeds of model and original at which this condition is satisfied are called corresponding speeds

In many hydraulic problems however viscous forces are unimportant compared with those due to inertia and in this case it may be proved that the corresponding speeds are proportional to the square root of corresponding dimensions Thus in ship model tests the corresponding speeds of model and original are proportional to the square root of their respective lengths These speeds give similar wave formations Viscosity the effect of which is relatively small prevents exact similarity of the lines of flow in the immediate vicinity of the vessels at these speeds and this introduces a scalar effect for which a correction can be made

In the case of a tidal model the correct propagation of the tidal wave is an all important factor The velocity of propagation of such a wave is proportional to the square root of the depth of the water through which it travels so that the times required for the wave to traverse corresponding distances in the model and the estuary will be proportional to the horizontal scale ratio and inversely proportional to the square root of the vertical scale ratio This determines the ratio of corresponding times and therefore gives the correct tidal period for the model If for example the horizontal scale ratio is 1 40 000 and the vertical scale ratio is 1 400 the time ratio is 1 2 000 and since the tidal period in Nature is about 12 hours 20 minutes the correct tidal period in the model is 22 2 seconds

If the effects of viscosity are small in comparison with those due to inertia as is the case in a model of suitable size all velocities will then be in the ratio of the square root of corresponding depths

DISTORTION OF SCALE

When constructing a river or estuary model it is seldom possible to adopt the same scale for both horizontal and vertical distances Especially in tidal models the horizontal reduction in scale has usually to be considerable in order to keep the model within reasonable dimensions and a scale of more than 18 in to 1 mile (1 in 3 520) is unusual a more common ratio being about 1 8 000 If this latter scale were also adopted for the vertical depths in a model of an estuary having a tidal range of say 33 ft the range in the model would only be 1/20 in and the current velocities would only be about 1/90 of those in the estuary In such a model the motion of the water would certainly not be turbulent as in the estuary and no motion of the bed materials would be likely to occur To avoid this difficulty the vertical scale ratio is made much less than the horizontal scale ratio Thus by making the vertical scale ratio 1 200 the tidal range in the case mentioned would be 2 in and current velocities would be 1/14 of those in the estuary

Reynolds in his investigations on models of estuaries of simple symmetrical form concluded that for a model to reproduce estuarine conditions the product of the cube of its maximum tidal range measured in feet multiplied by the ratio of the vertical and horizontal scales should not be less than 0 09 and while in an estuary of non symmetrical shape a smaller value of the criterion may be adopted it does give an approximate idea of the scales which are likely to give good results in any particular case

It may be of interest to note that this distortion of scale is usual in Nature small streams flowing through alluvial ground having much steeper side slopes and gradients than large rivers of similar regime in similar ground In a very large river such as the Mississippi the Ganges or the Irawadi the maximum depth will rarely exceed 1 100 of the maximum width while in a small stream in similar ground this ratio will seldom be less than 1 5

---

* From a Friday evening discourse delivered at the Royal Institution on April 13

A moderate distortion of scale, either in an estuary or river model, would therefore appear to be rather an advantage than otherwise provided that the side slopes which would be necessary in the model to reproduce those in the estuary do not exceed the natural angle of repose of the bed materials Since this angle is only about 30°, there will usually be points in a model where the sand is unable to stand up to the required slope, and where in consequence, the depth of the channel or the height of the banks will be less than in the estuary The actual slopes in most tidal estuaries are, however, very slight indeed, and experience shows that the areas over which the angle of repose would be exceeded in a model do not usually amount to more than a very small fraction of the whole In such cases, if thought desirable a slight stiffening of the bed material with an admixture of clay will usually enable the required slope to be maintained

BED MATERIALS

A criticism often levelled at the use of tidal and river models is that since the actual bed material is usually a not very coarse sand unless something of the nature of an impalpably fine powder is used in the model, the grain size and textual roughness of the bed will not be reduced in the same proportion as the remainder of the model The idea that the bed material should of necessity be scaled down in size would appear to be based on two misconceptions The first is that the resistance to flow is appreciably affected by the surface roughness Actually, in any model of a large river or estuary having a sandy bed the resistance is almost entirely due to eddy formation caused by curves and irregularities in the sides and by irregularities in the depth, the magnitude and effect of which are overwhelmingly greater than that of a change in the textual roughness of the surface itself

The second misconception is that because the current velocities are reduced in the model, the size of particle which they will move is necessarily correspondingly reduced This overlooks the well known experimental fact that a given mean velocity of flow has a much greater scouring effect in a shallow than in a deep channel

Investigators of the problems of silt and scour in Indian and other rivers and canals have found that rivers and canals of similar cross section but differing in size, and having the same bed materials, are subject to similar scour or siltation if the mean velocity is proportional to d^m, where d is the depth and where the value of m as given by various observers varies from about 0 45 to 0 64 All agree that the value is in the neighbourhood of 0 5, and if it were actually 0 5, two similar channels in the same bed material would scour or silt similarly if their velocities were proportional to the square roots of their depths But this is the ratio of velocities adopted for purely hydrodynamic reasons in tidal models, so that it would appear that materials of approximately the same grain size and density as comprise the moving sand banks in the estuary or river, should logically be used for the model Actually the determination of the best material and grain size is a matter for experiment, that which gives the best coincidence with Nature being the one to be adopted

In some German laboratories, working on problems of one-way river flow, a technique has been developed in which bed material considerably coarser and somewhat less dense than that found in the river is used At the same time the slope of the bed is increased This has been found to prevent the formation of sand ripples, which occur with some combinations of sand and velocity of flow On the other hand, in recent work on models of the Mississippi River at the U S Waterways experimental station at Vicksburg, a sand has been used having a diameter (0 0107 in) about a third of that of the somewhat coarse sand in the river and has been found to give excellent agreement with observations in the river itself

THE SILT PROBLEM

Many estuaries carry a considerable amount of silt of a colloidal nature in suspension This is originally brought down by the rivers feeding the estuary It tends to coagulate and to be deposited, forming silt banks especially where the fresh river water meets the saline water from the sea, and in a model of any silty estuary this effect needs to be reproduced

An examination of samples of the river waters enables the proportion of silt carried in by these to be determined, and the introduction of this proportion in the river water supplied to the model does not present any great difficulty In order to ensure that this shall tend to be deposited at the same place in the model as in the estuary, it is necessary to reproduce, in the correct ratio, the coagulating effects of the sea water The matter is somewhat complicated by the fact that, while the ratio of the distances through which a given particle has to sink through corresponding depths equals h/H, the corresponding times in which this is to take place are in the ratio $\frac{l}{L} \sqrt{\frac{H}{h}}$ It follows that the actual rate of fall of a particle in the model should be greater than that in the estuary in the ratio $\frac{h}{H} \frac{L}{l} \sqrt{\frac{h}{H}} = \frac{L}{l}\left(\frac{h}{H}\right)^{3/2}$ This greater rate of fall can be produced by increasing the size of the particles, either by using silt of greater coarseness, or by using some coagulating medium more effective than the salts in sea water In the various models I have constructed, the colloidal silt from the estuary itself has always been used, and alum solution has been used as the coagulating medium, experiments having been carried out in each case to determine the exact degree of concentration of this solution required to give the correct rate of deposition in the model

SEVERN MODEL

In 1926, the Severn Barrage Committee of what was then the Department of Civil Research decided that the only way to investigate the probable effect of a proposed tidal power barrage across the Severn estuary was to construct a working scale model Such a model, to a horizontal scale of 1 8 500 and a vertical scale of 1 200, was made in the Engineering Laboratories at the University of Manchester

The information required from the model was (1) The effect of the barrage on the tidal levels above and below its site, at all points between Barry and Gloucester (2) The effect on the tidal currents (3) The effect on the configuration of the sand banks and especially of the navigable channels (4) The effect on siltation above and below the barrage (5) The effect on sewage disposal (6) The effect on flooding in times of flood discharge from the rivers entering the estuary

The available data comprised details of a survey of the upper estuary carried out by Capt Beechey in 1849, along with Admiralty charts of the lower estuary of about the same period and some tidal observations from Penarth and Avonmouth and a few points in the upper estuary

These were supplemented in 1927 by the Hydrographic Department of the Admiralty, which took samples of the water at various points in the estuary, from which the salinity and silt contents were determined, samples of the bed materials, additional tide curves, float and current observations, observations on the Severn bore and, finally, a detailed survey of a large part of the estuary above and including the site of the barrage This in conjunction with Admiralty charts of the lower estuary, enabled the general configuration of the estuary at two times approximately seventy eight years apart to be compared, and these two surveys were used as a basis of calibration of the model

In the first place, the bed of the model was moulded in sand to the 1927 survey, after which a series of tidal observations were made at its seaward end, at the point corresponding to Penarth The mechanism and the form of the plunger producing the tides were adjusted by successive trial and error until the correct tidal curves were obtained at the seaward end of the model As the tidal wave advances up the estuary, considerable changes take place in its height and form, and a comparison with observations in the estuary shows that these changes are closely reproduced in the model

A comparison of the distances travelled by floats dropped at corresponding points in the estuary and model also shows a very close agreement, while the behaviour of the Severn bore, which was well developed in the model, shows an almost uncanny agreement, both as regards its height and rate of travel, with the behaviour of the original as determined by the Admiralty Survey party

After having obtained the correct tides, tests were carried out to determine the best bed material Twelve materials were tested in all, ranging from powdered pumice on one hand to emery on the other In each case the bed was moulded to the Beechey survey of 1849 and was surveyed after the number of tides (55,200) required to bring the date to 1927 The material which gave the closest agreement with the estuary survey of 1927 was found to be a silica sand about 25 per cent finer in grain than the sand in the estuary, and this was then used for all further work With this particular sand a comparison of the configuration of the model and of the estuary at the end of the period showed a good general agreement, especially in that part above the site of the barrage The general agreement, in fact was such as to indicate that when modified by the introduction of the barrage, the effect of this in the estuary might be expected to be very similar to that in the model

The tests to determine the effect of the barrage are carried out in pairs In the first of each, the bed of the estuary is moulded to represent the 1927 contours and a test is carried out without the barrage, surveys being taken at the end of each 10 20, 30, years The bed is then remoulded to the original state, and the test is repeated with the barrage installed and in operation, surveys being taken at the same intervals of time as before The complete results of these experiments have been embodied in an appendix to the report of the Severn Barrage Committee of the Economic Advisory Council

GENERAL REMARKS

The successful use of a tidal model depends largely on its being of a suitable scale, and on the possibility of being able to reproduce with reasonable accuracy the physical factors tending to produce movement of the bed materials As regards the scale, the largest scale which the available space permits is advisable This is partly because the necessary distortion of scale becomes less as the scale is increased and partly because it enables details to be developed and studied more accurately

Much also depends on the conformation of the estuary and on the tidal range, but for the average estuary, for investigating the effect on the navigable channels, the horizontal scale should not be less than about 9 in to the mile (1 7,040) With a tidal range of 30 ft, the Reynolds' criterion in such a model will be satisfied if the vertical scale is about 1 214, giving a vertical exaggeration of scale of 33 1 If circumstances permitted of a horizontal scale of 18 in to 1 mile, the vertical scale could be 180 1, which would reduce the exaggeration to 19 6 to 1 and obviously increase the usefulness of the model

As regards the factors tending to produce movement of the bed material, the one factor which is continuously in operation is the scour of the tidal currents, and these can be reproduced with sufficient accuracy in a model The currents, especially in the riverine part of the estuary are modified by seasonal changes in the river flow, and this factor can also be reproduced, given a knowledge of the probable magnitude and sequence of floods and dry periods. Where the estuary is exposed to some prevailing wind, the action of this can also be reproduced by means of fans adjusted so as to produce surface waves of the required height.

One factor which cannot be reproduced is the effect of violent gales, the incidence of which, both as regards time and direction, is casual. It is true that over a long period, where there is no prevailing gale direction, the effects of such extraneous forces may be expected partially to counteract each other; but on the other hand one such gale may produce changes in an exposed estuary greater than would occur in months or even years of normal ebb and flow.

For this reason, close agreement between model and estuary over a definite period of years is scarcely to be anticipated. Close agreement can only be expected where the estuary is comparatively sheltered and where the effect of the ebb and flow currents is all important. For this reason, a model is likely to be more successful of an estuary in which the physical features are such as to give rise to well defined currents, and in which the tidal range is large so that the strength of these currents is also large. From this point of view the upper Severn estuary, with its 40 ft. tidal range and current velocities approximating 10 knots at places, is an almost ideal subject for model investigation.

Another difficulty in attempting to reproduce all the changes in an estuary over a long period of time is that of reproducing coastal erosion. In many cases this is comparatively small in Nature, but where it is large the difficulties of finding a material which will erode at approximately the correct rate are great. Where this is necessary, it can only be done by extended experiment. In spite of the difficulty, however, experiments now in progress on a model of the Rangoon estuary (by Sir Alexander Gibb at University College, London) show that it is possible to reproduce this effect. This model, in which the effects of coastal erosion and of the monsoon gales have been incorporated, represents probably the most remarkable investigation of this type yet attempted.

Generally speaking, the great usefulness of an estuary or river model lies in its power to indicate the probable effect of artificial changes such as may be produced by the introduction of a barrage, or training walls or bridge piers. Such changes affect the tides and the set and velocity of the currents to an extent and in a manner which is reproduced with close accuracy in a model. In so much as an increased velocity causes scour and a reduced velocity causes deposition, if the bed material is moved the movement caused by the change will be in the same direction and of the same general kind as in Nature, and experience shows that in favourable circumstances good general agreement, both quantitative and qualitative, can be obtained.

Some estuaries owing to their physical characteristics are not suitable subjects for model investigation, but at the worst such an investigation gives information as to the changes in the velocities and directions of the currents, from which valuable deductions as to the probable effects on the bed may be made.

South African Plants Poisonous to Stock

THE subject of plants poisonous to cattle is of perennial interest to pastoralists which is receiving in South Africa the scientific attention it needs. The Veterinary Services and Animal Industry Branch of the Department of Agriculture of the Union of South Africa now has a team of workers (Onderstepoort Veterinary Research Station) consisting of Drs. Steyn and Quin, veterinary research officers, Dr. Claude Rimington, chemist working as a research fellow under the Empire Marketing Board and Dr. A. C. Leeman, botanist attached to the Division of Plant Industry, Pretoria. The first two numbers of the *Onderstepoort Journal*, which is to be issued quarterly in continuation of the annual reports of the Station, contain several interesting papers on the subject.

In a series of six papers in the first issue, Dr. Steyn deals on broad lines with poisonous plants. It is shown that it is possible to develop in animals a considerable degree of tolerance to certain poisonous plants by feeding them with small, but increasing, quantities, whilst with other plants continued ingestion of small quantities may even cause sensitisation or produce cumulative effects. An interesting side issue is the proposal to use sodium chlorate as a weed killer for the rag worts (*Senecio* spp.), which are responsible for poisoning stock both in New Zealand and South Africa. Before adopting it, its toxicity to stock has been carefully tested and found so low that it is regarded as a safe means of destroying these weeds.

It is still uncertain whether the disease known as 'lathyrism', common in certain parts of India, is due to use of *Lathyrus sativus* peas as a foodstuff, and for that reason a proposal to use *L. sativus* hay as a feeding-stuff in South Africa has been investigated. The hay proved innocuous to rabbits, sheep and cattle even when fed in comparatively large amounts, but was poisonous to horses. Great care was taken to make sure that the hay was entirely derived from *Lathyrus sativus*, and these observations support the view that this plant is the cause of 'lathyrism', and that horses are particularly susceptible to its action.

These studies are continued in the second number of the *Journal* where Drs Rimington and Steyn produce an interesting study of the poisoning of Angora goats suspected to be due to *Psilocaulon absimile* This plant contains malic tartaric and oxalic acids the last mentioned being present to the extent of 8 6 per cent which may therefore well be the toxic constituent concerned On this point however the authors say they have evidence of the presence of a second toxic substance on which a further communication will be presented in due course Six papers entitled Studies on Photosensitisation by Dr Quin have arisen from an attempt to ascertain the cause of geeldikkop a disease of small stock characterised by photosensitisation and by a generalised icterus The disease has been generally associated with ingestion of *Tribulus* spp but it is pointed out that there are well authenticated cases in which *Tribulus* cannot be the cause In view of the occurrence of photosensitisation in geeldikkop a number of fluorescent substances such as eosin erythrosin acriflavin and quinine were administered to sheep but though these all caused photosensitisation in no instance was icterus produced

The association of *Tribulus* with this disease has naturally led to a chemical examination of plants of this genus Already in 1928 Dr Quin had found that administration of the expressed juice of *Tribulus* to sheep caused death the chief symptoms being discoloration of the conjunctivæ the blood vessels having a chocolate brown colour Examination of the blood indicated the presence of an abnormal pigment suspected to be methæmoglobin These observations have been confirmed and Drs Rimington and Quin now show that the lethal factor is potassium nitrite which is only present in traces in the plant but is produced when the ground plant is placed in water by the action of an oxidation reduction enzyme system similar to that present in the potato on nitrates which may occur in considerable quantity in the plant These interesting observations however leave the association of *Tribulus* with geeldikkop unexplained since as Dr Quin points out in a subsequent paper no fresh or dried *Tribulus* material dispatched to the Onderstepoort laboratory or cultivated there has produced a case of true geeldikkop on administration to sheep although several species of *Tribulus* can definitely be held responsible for outbreaks of the disease in the Karroo areas of Cape Province (see also NATURE 132 178 July 29 1933)

Two species of *Hypericum* a genus associated with the production of photosensitisation in animals in Europe have also been examined and found to produce this effect but unaccompanied by icterus *Lopholæna coriifolia* a plant suspected as a possible cause of one outbreak of geeldikkop was found to contain an active substance producing marked fatty changes in the liver but in no way characteristic of the conditions found in geeldikkop Two species of *Lippia* however did produce both icterus and photosensitisation but the symptoms were much less severe than those seen in true geeldikkop Although a final explanation of the cause of this mysterious disease is still to be sought it is clear that progress is being made and incidentally a number of interesting observations on plant chemistry and on the effects of minor plant constituents on animals are being accumulated

Obituary

PROF W M DAVIS

EVERY active worker in geology in geography and in oceanography will feel that the death on February 5 of William Morris Davis at the age of eighty four years is the passing away of a historical figure in science His life when written will be the story of the development of geomorphology and of the creation of an American school of international prestige His whole career more than sixty years of active scientific work exhibits the regular series of interests of many great investigators detailed studies in a relatively limited scientific field next broader applications supported by intense varied and enthusiastic studies to test and support the same—and finally the close of life devoted to a single line of investigation often the ploughing of a lonely furrow

Davis s first field was the southern part of New England including New Jersey and his publications extend to every type of its topography About 1880 he concentrated on the Hudson and Connecticut valleys These lie in a region of tilted blocks produced by faulting the initial fault scarps subjected to extensive erosion As Davis showed the cliffing may be completely altered and these cliffs were termed *fault line scarps* He was fascinated by these studies of erosion and he summarised his many publications in The Rivers and Valleys of Pennsylvania and The Rivers of Northern New Jersey He pictured the work of unchecked erosion on the land by weathering and by water in all its stages finally culminating in a reduction of sea level the *base level* towards which the land surface constantly approaches but which it can never reach’ Here he encountered the established views in respect to marine abrasion and he characteristically set to work on investigations in Europe Asia and South Africa to establish the validity of his views He also studied glacial (recent and Permian) erosion faulting and shorelines with a certain disregard of local researches His work on shoreline topography the continental slopes and marine shelves bristles with original ideas but the soundings on which he was depending were occasionally woefully inaccurate though I cannot recall that these were such as to invalidate his conclusions as to embayed shorelines It will be interesting to mention that in a letter I received more than twenty five years ago he discussed the down faulting of a former extension of the Deccan in the area now occupied by the Indian Ocean, the area of the investigations of the "John Murray Expedition"

It is impossible to refer in any detail to the gigantic output of Davis in these thirty years In his own continent he found every type of country, from completely desiccated to extreme moistness, almost tropical heat to perpetual cold, and he studied the phenomena in respect to each, thus gradually building up that study of the visible earth forms on which modern geography is so largely based He claimed none of his conceptions as new but he looked at every phenomenon through new glasses, and he codified all phenomena to form almost a new science During all these years Davis was teaching not only in his own University, Harvard but also lecturing almost everywhere he was asked His exposition was clear and he used every possible device, particularly solid and composite sections, to make his views clear to his auditors and subsequent readers dismissing all possible opposition, and sometimes ignoring the evidence on which it was based His scientific opponents could not approve where, as in science, views are nicely weighed in the balance, but undoubtedly he gained an immense following in America and stimulated both teachers and the public to observe By many he was regarded as an inspired teacher, but his methods were of more use in popularising science rather than in stimulating research His popular works on geography deservedly secured an immense circulation for the visible world was therein a connected system, made clear by pictorial methods largely original Davis came at the right time

Davis's third period commenced about 1912 when he began to feel a mighty interest in the coral reef problem, upon which he published more than forty papers, actively pursuing the subject until his death He thoroughly enjoyed the subject, for it became necessary for him to travel extensively, and he saw many new faces and met many new types of mind He visited the West Indies several times, with longer expeditions to Fiji and New Caledonia, with calls upon the Great Barrier Reef, Tahiti, and many other places While he criticised Agassiz for the shortness of his visits, and his lack of detailed examination, his methods were much the same, and every locality had to fall into his line He paid little attention to animals and plants and their dependence on the favourable conditions of their environment He seemed to love to indite fierce letters in which he was entirely unsparing of his opponents' feelings, but, when, very occasionally, he wrote a letter in his own hand about himself, he revealed a personality happy in spite of great griefs, a man to be loved Shaler he held in great affection and it gave him joy to write "The Coral Reef Problem", 1928, in the Shaler Memorial Series, a book of value for all time, with its full discussion of embayed shores and unconformable contacts He felt himself inspired Did not he, Dana and Darwin all share the same natal day in different years—and must they not be right ? What was the use of further expeditions when all seemed to Davis so clear ? Why in his necessary travels did the present writer sit down for months on *five occasions* to look at separate reefs ? "A waste of time !" Davis was very human, he deemed it his duty to fight here to gain a great peace hereafter J S G

PROF R CHODAT

GENEVA, which has always had a great name as a school of botany, has suffered a great loss by the death on April 29 of Prof Robert Chodat at the age of sixty nine years A worthy follower of de Saussure and de Candolle, Chodat upheld the traditions of his predecessors by the wide outlook of his botanical studies, and the thoroughness of his investigations

Appointed to the professorship in Geneva in 1891 after studying in Basle and Geneva, Chodat has been responsible during the past forty three years for the development of a first rate laboratory, herbarium and botanical library The lack of university botanical gardens, which he frequently deplored, necessitated his researches being centred in the laboratory, and here he elaborated those methods of pure cultures of Algæ which led to such important results His book on the polymorphism of the Algæ put him at once in the front rank of algologists and stimulated many workers to embark on this line of research More recently he had taken up mycological investigations, and his sound knowledge of physiological chemistry enabled him to advance considerably our knowledge of fermentative processes

Chodat did not, however, confine himself to investigations in the laboratory A visit to Paraguay in 1914 enabled him to study the structure and habits of its plants and resulted in the publication of an important flora of that country Repeated visits to Spain and Portugal and the Balearic Islands with his students gave him a comprehensive knowledge of the Mediterranean flora, of which he published some interesting accounts

Chodat rescued from neglect the Alpine Garden at Bourg St Pierre by attaching it to the University of Geneva, and the vacation courses he gave there every summer attracted many students from England and elsewhere, numerous investigations carried out there were published by the Botanical Society of Geneva Chodat, like other Swiss botanists, was greatly impressed by the numerous Mediterranean plants found in the upper Rhone valley of Switzerland, and his careful observations led him to the conclusion that many, if not most, of them had been distributed from the south across the mountain passes and had not, as was formerly supposed, immigrated by way of the Lake of Geneva

Chodat was a good systematist, as is shown by his monograph of the Polygalaceæ but the wideness of his interests is attested by his publications on fossil plants and genetics as well His wide and philosophic outlook is mirrored in his excellent 'Principes de Botanique", which is in every way an admirable textbook A stimulating teacher, Chodat trained many first rate botanists whose researches do credit to their master So eminent a botanist was sure to receive due recognition abroad, and Chodat was awarded honorary degrees by the universities both of Manchester and of Cambridge, and last year he was awarded the Linnean Medal of the Linnean Society of London, of which he had been a foreign member since 1914 Unfortunately during the last few years, partly due to systematic overwork, he suffered from ill-health, and shortly after his return from a visit to Egypt and Palestine he died after a short illness He will be greatly missed in England, as well as Switzerland, for he was a frequent and welcome visitor to this country, where he had many friends F E W

WE regret to announce the following deaths

Dr M G Foster son of Sir Michael Foster and author of numerous papers on balneology and climatology, on June 16 aged sixty nine years

Dr C E Grunsky, consulting engineer, president of the California Academy of Science, president in 1924 of the American Society of Civil Engineers, an authority on water engineering and supply, on June 9, aged seventy nine years

Prof Thomas H Macbride, emeritus president of Iowa State University, professor of botany in the University in 1884–1914 an authority on Myxomycetes on March 27, aged eighty six years

News and Views

Sir Robert Mond

THE honorary degree of LL D was conferred by the University of Toronto, on June 6 at the time of the annual Convocation, on Sir Robert Mond Sir Robert who was knighted in 1932, is the eldest son of the late Dr Ludwig Mond F R S and has inherited his distinguished father's scientific tastes, as is shown by his association with many learned societies, including the Faraday Society of which he is a past president Another side of his scientific activity is shown by his interest in archæological studies and he is president of the Egypt Exploration Society Sir Robert was one of those chosen to receive an honorary degree at the opening of the new wing of the Royal Ontario Museum in the autumn of 1933, but was unable to visit Toronto until the recent Convocation The Royal Ontario Museum owes Sir Robert a great debt of gratitude, not only for actual gifts of great value, but also for his constant advice during the development of the Museum from very small beginnings His most recent gift is in sharing with Dr Sigmund Samuel, of Toronto, and Bishop White, formerly of Honan, China, now professor of Chinese literature in the University of Toronto, in the donation of a very valuable library of Chinese books, now known as the Chinese Library of the University of Toronto, and containing more than forty thousand volumes

Excavations at Tell el Duweir, 1933-34

AN exhibition of the material discovered by the Wellcome Archæological Research Expedition to the Near East in the second season's excavation at Tell Duweir, 25 miles south west of Jerusalem, under the direction of Mr J L Starkey, will be held at the rooms of the Palestine Exploration Fund, 2 Hinde St, W 1, on July 2–21 The work of the Expedition during the past season has now established the extent of the Early Copper Age site as covering at least 150 acres It includes the remains of a large dolmen The upper terrace of a limestone ridge flanking the Tell across the western valley was found to be honeycombed with caverns which had been artificially enlarged and adapted as dwellings in the Early Copper Age and re used at a later date as burial places Metal here occurred rarely but unique for this early period was a heavy gold bead contemporary with proto early dynastic age in Egypt Rough castings from moulds were found on the surface Pottery was hand made, and small pottery bowls showing a sharp impress afforded evidence of textiles A large necropolis lower down the side of the ridge yielded contracted burials in small oval chamber tombs with a shallow shaft In these were daggers or darts food vessels etc This cemetery is equated with the Egyptian Old Kingdom At the north west corner of the Tell, the Hyksos fosse and revetment were uncovered, and the later system of defence was traced in its entirety The Persian residency superimposed on the Jewish palace fort destroyed in the sixth century B C was cleared

AMONG other discoveries by far the most interesting and important was that of a small temple found in clearing the fosse This consisted of a square sanctuary containing an altar and shrine, with two small store chambers Free standing benches were arranged on three sides of the sanctuary This building had been destroyed by fire and its contents were thus found complete, although damaged by the flames They consisted of a large number of ceremonial vessels and utensils, toilet articles, etc The most important is the painted pot, of which the inscription has already given rise to much discussion among experts, as to the affinities of the script and its translation Other exhibits from the temple include a number of scarabs bearing the name of Amenhotep III, notably one recording the killing of 102 lions in the tenth year of his reign. Ivory, glass and faience objects include a beautiful small ivory mask. The art of this and other carved objects, including a carved hand, three-quarter life size, suggest an artistic relation of some kind with Tell Amarna. Some ivories, much calcined by fire, including a remarkable perfume vase fashioned from an ivory tusk, are delicate examples of the engraver's art. A plaque of Rameses II points to the destruction of the temple having taken place not later than 1262 B.C., but until the levels below the temple have been examined, it is not possible to suggest the date of its foundation.

Fuel Research in Great Britain

In the course of a normal year, about six hundred visitors are received at the Fuel Research Station, Greenwich, but the Fuel Research Board has come to the conclusion that, in addition, a general visitation would be a valuable means of bringing the Station's work before industry and the public. The first visitation was held on June 25, when about three hundred guests were received by Sir Harold Hartley (chairman of the Fuel Research Board), Dr. F. S. Sinnatt (Director of Fuel Research) and Sir Frank Smith (secretary of the Department of Scientific and Industrial Research). The visitors were given an opportunity of seeing practically all the modern methods in the study and treatment of coal. Demonstrations of coal washing, by wet and dry systems, attracted a large number of visitors. A rotary coal dryer and mill for pulverising, together with such burners as the Grid and Vortex for the powdered fuel, were shown in operation. Coal-oil suspensions showed one line along which research is being conducted with the view of making coal a more flexible fuel. Specimens of the liquid products of low temperature carbonisation were shown. But perhaps the focus of interest for most visitors was in the hydrogenation building, where compressors for delivering hydrogen at a pressure of 200 atmospheres, and the converters in which the reaction takes place at that pressure and a temperature of 480° C., were demonstrated in action.

Foot-and-Mouth Disease

Some interesting information was given by the Minister of Agriculture in the House of Commons on June 25, when Sir Arnold Wilson asked two questions on the subject of foot and mouth disease at the request of the Parliamentary Science Committee. Sir Arnold asked what progress has been made by the Foot and Mouth Disease Research Committee during the last two years, and what, broadly speaking, the results of its investigations have been, more particularly in the direction of preventive treatment by inoculation. Mr. Elliot promised a memorandum on the subject in reply and stated that the Fifth Progress Report of the Committee is in course of preparation, and is expected to be available in the autumn. Sir Arnold also asked whether the Committee has considered the possible connexion between the quality of the food of cattle and the incidence of this disease, and whether the Committee is dealing with the question of the prevention of foot and mouth disease by a combination of high quality food and improved hygiene. Mr. Elliot in his reply stated that the Committee has advised that there is "no evidence to show that diet or hygiene, or a combination of both, have any influence on the spread of foot and mouth disease. Clinical observations and experimental work carried out by the Committee have in fact shown that animals in very good condition may contract the disease in a more severe form than animals in poor condition." Referring to the possible spread of foot and mouth disease by imported straw, in answer to a question by Col. Acland Troyte, Mr. Elliot stated that the importation into Great Britain from countries where foot and mouth disease exists of hay and straw for use as fodder or litter for animals is prohibited, and imported straw used for packing merchandise has to be destroyed after use; there does not appear to be justification for further prohibition of the importation of this material.

Educational Sound Films

Under the auspices of the British Film Institute, 4, Great Russell Street, London, W.C.1, a private demonstration of educational sound films was presented at the Academy Cinema, London, on June 21 before teachers and educationists. As Mr. H. Ramsbotham, M.P., Parliamentary Secretary to the Board of Education, pointed out in his introductory address, such films must not be accepted without reservation, for they should always be looked upon as being supplementary to the teacher himself. The production of the films shown was a piece of pioneer work and experimental in character, and the venture augurs well for the future of the cinematograph in education, especially if the producers receive the constructive criticism from teachers for which they ask. There is little doubt that, provided it is not abused, the sound film will prove an important asset to the teacher of the future. The seven films presented on this occasion clearly showed not only the expert film producers we have at our command, but also where the film will be a useful aid and where it will prove an unwelcome intruder.

The films of the life history of the thistle, the growth and irritability of roots, and the physiology of breathing were examples of good educational films—useful tools in the hands of a responsible teacher. They showed the value of the cinematograph film in photomicrography and in demonstrating those types of motion too slow to be watched normally. The film of wheatlands in East Anglia, too, was a good lesson in economic geography and rural science, and demonstrated the possibilities of the film in transporting a class to the actual scene of action, which otherwise has to be done, rather inefficiently, by laborious verbal teaching and much reading. Such films indicate the lines along which it is to be hoped the cinematograph in education will develop. On the other hand, certain films shown depicted the dangers inherent in the cinematograph as a teaching factor That on kitchencraft, for example, merely illustrated the processes involved in making a pork pie Most domestic science teachers, we think, would prefer their pupils to learn such a lesson by doing it themselves But this is only the experimental stage, and though there is much to learn, a great deal of good work has already been done To add to their value, the films are produced under authoritative direction The films shown were made by Gaumont British Instructional, Ltd, 12 D'Arblay Street, Oxford Street, W 1, who are to be congratulated on the excellent production, beautiful photography and useful running commentary The whole performance will be presented later in provincial towns

Repton School Science Society

THE Repton School Science Society held its triennial conversazione in the Science School on June 22–23 when some fifty demonstrations and exhibits in biology, chemistry, and physics were shown by members of the Society In the biology section a demonstration of the circulation of the blood in the tail of a tadpole was shown both the pulse and the corpuscles being clearly visible The laboratory aquarium and numerous specimens collected by the members were also shown Two points of interest in the chemistry section were a demonstration of the spinning, bleaching, and souring of rayon by a home made model, and a set of experiments on testing the hardness of water and the various methods of water softening Perhaps the most conspicuous feature of the physics section was a lecture on the electric spark, which included an elementary account of the mechanism of the spark, illustrated by various experiments on ionisation The conversazione was well attended, and the visitors were impressed by the able manner in which the lectures and demonstrations were given

Architects' Unemployment Committee's Exhibition

A NATIONAL crisis must naturally affect immediately those fields of activity most removed from the provision of essential necessities, and at the close of 1931 architects felt very severely the curtailment of their work due to restrictions required by economy The Royal Institute of British Architects, in this emergency, set up a relief scheme in the form of payment for useful work of a public character made possible by subscriptions to a relief fund started by this and other kindred institutions A sum of nearly £12,000 was collected the whole of which has been expended in salaries and incidental costs in making surveys which should be of considerable value The results are displayed on maps and models now on exhibition at 7, Bedford Square, London Here on the 25 in ordnance map may be seen indicated by colours the disposition of public, commercial and industrial buildings, business premises, and private and municipal housing over the whole of the London district and much of Kent A 6 in map shows London factories, shops, clubs, banks, and public buildings A survey of the heights of London buildings has also been made and recorded An interesting model of the London area is displayed showing the growth of London by centuries from Roman times to the present day The information which can be grasped from the exhibition at a glance is most striking and the maps should be of great value to Government and municipal departments The display suffers from inadequate space, and though ingeniously arranged on curved surfaces, a comparison of the Hampton Court area on the walls with Greenford on the ceiling at some distance is not easy The exhibition was opened by Lord Snell on June 22

Leadership in Industry

IN the Mather Lecture of the Textile Institute delivered on May 25, Mr A P Young (*J Text Inst*, May) gives a stimulating discussion of the functions and opportunities of industrial leadership Reviewing the origin of the scientific era and the imperative necessity for adequate leadership in this age of power production, he sees in it the opportunity for many of the inspired qualities and the spirit of adventure which have animated previous pioneers of creative thought Such leadership should be capable of harnessing to the task of industrial evolution, world co operation and reconstruction the increasing productivity of the human unit, the accelerated rate at which raw materials are brought into service the development of the electrical power era the diminution of the time lag between discovery and industrial application, the linking of production and distribution This must be done on a basis of planned co operation and leadership will function largely through its ability to stimulate the essential spirit of team work

MR YOUNG discusses the qualities required in the industrial leader of this calibre among which he lists this ability to foster team work, creative imagination intellectual sincerity and moral courage, power to co operate with others, knowledge of administrative principles capacity for delegating authority and scientific and technical knowledge He emphasises the importance of a science as well as an art of management and asserts that education for management is one of our greatest national needs, the need extending to the training of foremen and supervisors as well as managers and leaders carrying high responsibilities Mr Young discusses in some detail the problems of planning and leadership in the textile industry laying stress on the service motive in industry He sees a great future for the textile industry when planned and led along such lines, and concludes with a plea for co ordination of the activity of the five research associations which now exist and for a five fold expansion of the industry's expenditure on research within the next five years

A Photographic Centenary

ON June 23, a gathering took place at Laycock Abbey, Wiltshire, to do honour to Henry Fox Talbot, who in 1834 in that house first succeeded in producing photographic impressions on paper Fox Talbot, who was born in 1800 and died in 1877, graduated at Cambridge in 1821, and became known for his original papers on mathematics, physics and astronomy In 1831 he was elected a fellow of the Royal Society and two years later became M P for Chippenham His experiments of 1834 were the outcome of an idea which had occurred to him when sketching the scenery of Lake Como with the aid of Wollaston's camera lucida, and they resulted in the development of Talbot's first process, photogenic drawing, described to the Royal Institution by Faraday in January 1839 The guests at Laycock Abbey on June 23 were received by Miss M T Talbot, the inventor's granddaughter, and an address on Fox Talbot's personality was given by his grand son, Prebendary W G Clark Maxwell Other addresses were given by Mr H Lambert, of Bath, and Mr A J Bull, president of the Royal Photo graphic Society A large exhibition of Fox Talbot's early apparatus and of his negatives and prints was arranged in the gallery and among these was prob ably the earliest existing photograph a window in Laycock Abbey

Blériot's Flight Across the English Channel

To commemorate the first flight by aeroplane across the English Channel by M Louis Blériot on July 25, 1909, twenty five years ago, a demonstra tion took place at his aerodrome at Buc near Paris on June 23 which was attended by the President of the French Republic, M Lebrun, Lord London derry and Sir George Clerk, the British Ambassador The old Anzani engined monoplane in which the flight was made was on exhibition, and in the fly past which closed the meeting modern French aircraft scattered flowers upon it At the time of the flight M Blériot was suffering from injuries to his foot and the crutches which he was using were strapped inside the fuselage During the afternoon, many displays took part in which a squadron of Hawker Fury fighters of the Royal Air Force joined and in a speech Lord Londonderry said that M Blériot found a new high road of the air, which, within the short period of six years from the first flight, was to be traversed, not by a single Englishman paying a return visit to the coast of France, but by British pilots in their thousands, flying to the help and defence of Louis Blériot's fellow countrymen

Recent Acquisitions at the Natural History Museum

An important donation to the Zoological Depart ment of the British Museum (Natural History) is a gift from the Rowland Ward Trustees of a mounted head of a female addax (*Addax nasomaculatus*) from the Sudan An abnormal elephant tusk from Uganda has been presented by Mr George Howard, of the Queen's Bays This tusk is of interest as showing an early stage in the formation of the so called 'four tusked elephant' Another donation of interest is that of three skulls of the so called dwarf elephant from the Gola Forest in Sierra Leone, the gift of Sir Arnold Hodson, the Governor of Sierra Leone These specimens would seem to substantiate the theory that this animal, known locally as the 'Sumbi', is merely the young phase of what has been termed the 'forest' elephant, which may be known by the name *Elephas africanus cyclotis* There has been presented to the Department of Geology a large and valuable collection of type and figured specimens of rhinoceroses from the lower Tertiary beds of Baluchistan, described and figured by the donor, Mr C Forster Cooper, a large collection of fossil invertebrates from the United States, collected and presented by Miss Mary S Johnston, and type specimens of three fossil fishes described by Prof H H Swinnerton, and presented by him An interesting collection of 727 pebbles, illustrating forms, origins, and materials, has been presented to the Department of Minerals by Mr E J Dunn of Melbourne, who commenced collecting so long ago as 1856

Mr J E Cooper has presented his herbarium to the Department of Botany of the Museum It contains about 2,000 sheets of well preserved flower ing plants, a large number of which are aliens The other specimens are chiefly from the London district, including parts now built over A collection of more than 700 plants has been made by Mr J E Dandy, assistant keeper in the Department, who accom panied an expedition to the Anglo Egyptian Sudan organised by Mr C G T Morison to study soil vegetation relations in an area where there is a big variation in rainfall The area west of the Nile shows a large range between the dry north and the Nile Congo divide in the south Collections were made in many areas which were previously little known, and it is probable that much of interest from the point of view of geographical distribution will result, particularly from that from the high massif of Jebel Marra

Fire Protection of Electric Generating Stations

In the *Electrician* of June 22 there is an interesting account of the method adopted for protecting the large power station of the Bristol Corporation at Portishead from fire, by means of carbon dioxide The great advantage of carbon dioxide for power house use is that it extinguishes the fire with little risk of interrupting the operation of the station The maintenance of a continuous supply of electric power is of the greatest importance in generating stations. The installation consists of carbon dioxide cylinder batteries centralised in a special building situated about 80 feet away from the station Main pipes connect the cylinders with control valves placed at convenient points for directing the gas in the event of fire Entirely automatic operation is arranged only for the transformer compartments, where thermostats are filled which operate the control valve The quantity of gas stored is such that any section pro tected by the system can be flooded with gas more than sufficient to extinguish any fire The draw backs to using chemicals having a water content in rooms containing live electric wires are well known In the event of fire arising in an alternator, there is an initial discharge of gas from ten cylinders As the rotor continues to revolve for about half an hour before it comes to rest, the initial discharge is liable to be dispersed and so the gas concentration might fall too low For this reason ten more cylinders are provided, each of which functions successively at intervals of three minutes and thus a safe degree of concentration is maintained

Interference between High-Power Radio Stations

A REPORT from Science Service dated May 29 states that Dr Balth van der Pol, speaking at a meeting of the Institute of Radio Engineers in Philadelphia has directed attention to the interference which may arise if the power of broadcasting stations is sufficiently increased Dr van der Pol reported that interference has been noticed in Holland between two distant high power European stations separated in wave length by more than 800 metres This interference has been attributed to interaction or cross modulation of the two sets of signals in the passage through the ionosphere (See B D H Tellegen NATURE 131 840 June 10 1933 V A Bailey and D F Martyn NATURE 133 218 Feb 10 1934) The effect is believed to increase rapidly as the power of the sending station increases and if the same phenomenon is found to exist in America, it may prove to be a practical limitation to the power at which radio broadcasting stations can be operated This would appear to be a new problem for the Federal Radio Commission to consider in the United States

Indian Physico-Mathematical Journal

READERS of NATURE may be interested in the *Indian Physico Mathematical Journal* which appears twice yearly It was founded in 1930 for the purpose of publishing original papers on mathematics and theoretical physics, under the editorship of Prof J Ghosh, Presidency College Madras, assisted by a board of eminent Indian scientific workers The latest numbers, which we have recently received contain many interesting papers representative of both the above subjects These form a definite contribution to science and are worthy of more than a local circulation The *Journal* does not belong to any particular institution, but exists solely to encourage research The annual subscription outside India is £1

Manuring of Vegetable Crops

LITTLE exact knowledge of the effectiveness of artificial fertilisers on vegetables is available and further, it seems doubtful whether good crops can be raised indefinitely with the use of artificials alone For these reasons, the Ministry of Agriculture has thought it desirable to collect all the possible information on the subject, and a bulletin compiled by A H Hoare entitled "The Manuring of Vegetable Crops" has just been published (No 71 1*s* net) It is recognised that for economic production a thorough understanding of the fundamentals of soil fertility and its relation to plant growth is required, and the first part of the bulletin deals with this subject in a concise and practical manner Special attention is directed to the possibilities in the less commonly used organic manures that are now available, the need of which is a matter of particular importance for growers on light soils The various types of crops, brassicas, roots, leguminous, potatoes, etc , are then dealt with in turn and the most suitable fertilisers to use in each case and the best time for their application are supplied The requirements of the small scale gardener or allotment holder are not overlooked, and where special instructions for crops intended for canning may be helpful they are included

Leaflets on Diseases of Fruit Trees

THE Ministry of Agriculture and Fisheries has recently issued five new advisory leaflets dealing with fruit tree diseases Leaf Scorch Glassiness and Bitter Pit of Apples (No 203) gives useful descriptions of these three physiological disorders outlines the conditions which produce them and suggests ways in which they may be avoided Advisory Leaflet No 205 (Apple Mildew) replaces Leaflet No 204 and emphasises the need for cutting diseased twigs well back, in order to remove all the fungus Gooseberry Cluster Cup Rust (No 198 , replacing No 209) describes the æcidial stage of the fungus *Puccinia Pringsheimiana* which spends its uredo and teleuto spore stages on certain sedges The æcidial stage occurs on the leaves and fruit of gooseberries causing malformation Control is obtained by hand picking diseased fruits, and removing sedges from the locality The die back disease of gooseberries is treated in Leaflet No 204 (formerly No 234) The fungus *Botrytis cinerea* kills the outer tissues of the stem, usually just above ground level, and the whole bush dies The fungus is usually a saprophyte and its attacks may be controlled by clearing away decaying material from the neighbourhood or spraying bushes with 0 4 per cent copper sulphate solution just before the buds open Powdery Mildew of the Vine (No 207) is an up to-date edition of Leaflet No 133

Research in Bacterial Chemistry

THE Medical Research Council announces the inauguration of new arrangements for further combined chemical and bacteriological investigations into the conditions which govern the life and multiplication of micro organisms causing disease These have been made possible by the generous co-operation of the Middlesex Hospital Medical School the trustees of the late Viscount Leverhulme and the Sir Halley Stewart Trust Accommodation and facilities are being provided at the Middlesex Hospital in the Bland Sutton Institute of Pathology and the adjoining Courtauld Institute of Biochemistry The investigations will be directed by Dr Paul Fildes, who has been appointed a member of the scientific staff of the Medical Research Council The other workers are Mr B C J G Knight, with a Halley Stewart research fellowship, and Dr G P Gladstone and Dr G Maxwell Richardson, holding Leverhulme research fellowships The arrangements took effect on June 1, and the support given by the co-operating bodies is sufficient for an initial period of five years

Leverhulme Research Fellowships

THE following Leverhulme research fellowships have recently been awarded, among others, for research in the subjects indicated Dr E Ashley Cooper, lecturer in chemistry, University of Birmingham (activity of enzymes of bacteria), Prof E E Evans Pritchard, assistant professor of sociology, University of Cairo, Egypt (detailed ethnological and sociological study of the pagan Galla of Western Abyssinia), Dr R MacLagan Gorrie, Indian Forest Service (correlation of erosion damage and grazing in forest lands), Miss M M Green, late Government Education Department, Nigeria (anthropological and linguistic research among the Ibo tribe of Southern Nigeria—joint research with Mrs S H Leith Ross), D Ll Hammick, fellow and tutor, Oriel College, Oxford (interaction of nitro compounds with aromatic bases and hydrocarbons), Dr H Stafford Hatfield (behaviour of crystalline substances in electric and magnetic fields), Dr L S B Leakey, part time lecturer in the Kikuyu language, School of Oriental Studies, London (prehistory of East Africa), Mrs S H Leith Ross, late Secretary, Board of Education, Nigeria (home and social life of the women of the Ibo tribe of Southern Nigeria—joint research with Miss M M Green), N E Odell, geologist to the Louise A Boyd Expedition to N E Greenland, 1933 (structure and metamorphism of the Franz Josef Fjord region of North East Greenland), Dr W H Taylor, assistant lecturer in physics, University of Manchester (application of X ray analysis to the investigation of the structures of organic compounds) Grants in aid of researches have been made to the following, among others Prof K A C Creswell, assistant professor of Muslim art and archæology, Egyptian University, Cairo, Egypt (researches on early Muslim art and architecture), Capt C R P Diver, Senior Clerk, House of Commons (South Haven Peninsula Survey, Studland Heath, Dorset (1) Physiography and history (2) Distribution of populations and ecology of several animal orders), J Reid Moir (prehistoric archæology), Mrs C F Tipper, University of Cambridge (plastic deformation of metals)

Museums Association

THE forty fifth annual conference of the Museums Association will be held at Bristol on July 2–6, under the presidency of Dr Cyril Fox The general theme of the conference will be the modernisation of museums and art galleries Dr Cyril Fox will deliver his presidential address on July 3 A discussion on folk museums will be opened by Dr R E M Wheeler Papers to be read include "The Popularisation of Geology" by Dr F S Wallis, "Maps in the Museum" by Dr F J North, and "Science and the Public Museum" by Prof A E Trueman On July 6, the Gaumont British Co will give a demonstration of "The Film in the Museum" Further information can be obtained from the Secretary, Museums Association, Chaucer House, Malet Places, London, W C 1

International Congress for Applied Mechanics

THE fourth International Congress for Applied Mechanics will be held at Cambridge on July 3–9 The following general lectures will be given Dr V Bush, "Recent Progress in Analysing Machines", Prof A Caquot, "Définition du domain élastique dans les corps isotropes—Courbes intrinsèques de résistance élastique apparante, et de résistance élastique vraie (endurance)", Prof J P Den Hartog, "The Vibration Problem in Engineering", Prof Th v Kármán, 'Turbulence", Prof Ernst Schmidt, "Heat Transmission", Prof G I Taylor, "The Strength of Crystals of Pure Metals and of Rock Salt", Prof Herbert Wagner, "Über das Gleiten von Kärpern auf der Wasseroberfläche" An extensive series of sectional papers will also be read Further information can be obtained from the Organising Secretary, Mr A H Chapman, Engineering Laboratory, Cambridge

Announcements

THE president and council of the Royal Society have recommended Viscount D'Abernon for election into the Society under the special statute which permits the election of "persons who in their opinion either have rendered conspicuous service to the cause of Science, or are such that their election would be of signal benefit to the Society"

THE meeting of the Faraday Society for the general discussion on Colloidal Electrolytes", originally announced for September 25–27, has been deferred to September 27–29 The date has been changed partly to suit the convenience of those who are travelling to the U S S R for the Mendeléeff Centenary Celebrations

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A principal of Watford Technical and Art Institute—The Clerk to Hertfordshire County Council, 28, Castle Street, Hertford (July 4) Five probationary forest officers—The Secretary, Forestry Commission, 9, Savile Row, London, W C 1 (July 4) An assistant lecturer in physics at University College, Nottingham —The Registrar (July 5) A junior scientific officer in the Admiralty scientific pool—The Secretary of the Admiralty (C E Branch), Whitehall, S W 1 (July 7) Three geologists on the Geological Survey of Great Britain and Museum of Practical Geology—The Director, Geological Survey and Museum, 28 Jermyn Street, S W 1 (July 9) A professor of surgery in the King Edward VII College of Medicine, Singapore—The Director of Recruitment (Colonial Service), 2, Richmond Terrace, Whitehall, London, S W 1 (July 14) An archæological commissioner in Ceylon—Director of Recruitment (Colonial Service), Colonial Office, 2, Richmond Terrace, Whitehall, S W.1 (July 31) A geologist in the Education Department of the Anglo Egyptian Sudan—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, London, S W 1

Exchange Forces between Neutrons and Protons, and Fermi's Theory

FERMI[1] has recently developed a successful theory of β-radioactivity, based on the assumption that transmutations of a neutron into a proton and vice versa are possible and are accompanied by the birth or disappearance of an electron and a neutrino.

This theory implies the possibility of deducing the exchange forces between neutrons and protons, introduced more or less phenomenologically by Heisenberg. (This idea occurred also quite independently to my friend, D. Iwanenko, with whom I have since had the opportunity of discussing the question.) Consider two heavy particles a and b, a being in a neutron and b in a proton state. If a becomes a proton and b a neutron the energy remains unchanged. Now these two degenerate states of the system may be linked up by a two-step process: the emission of an electron and a neutrino by the neutron a which becomes a proton, and the ensuing re-absorption of these light particles by the proton b which becomes a neutron. The energy of the system will be in general not conserved in the intermediate state (compare the theory of dispersion). The emission and re-absorption of a positron and neutrino may also take place[2]. In this way the two degenerate states of the system considered are split into two energy states, differing by the sign of the exchange energy.

Since the rôle of the light particles (ψ-field) providing an interaction between heavy particles corresponds exactly to the rôle of the photons (electromagnetic field), providing an interaction between electrons, we may adapt for our purposes the methods used in quantum electrodynamics to deduce the expression for Coulomb forces.

Putting $\psi = \psi_0 + g\psi_1 + g^2\psi_2 +$, where g is the Fermi constant ($\sim 4 \times 10^{-50}$ erg cm^3), and using the theory of perturbations and retaining only that part of ψ which corresponds to the absence of light particles in the initial and final states, we obtain

$$\left(H_0 - i\hbar\frac{\partial}{\partial t}\right)\psi_2 \sim \left(K \mp \frac{1}{16\pi^3\hbar c r^5} I(r)\right)\psi_0,$$

where K is an infinite constant, r is the distance between a and b and $I(r)$ is a decreasing function of r, which is equal to 1 when $r \ll \hbar/mc$ (m is the mass of the electron). Neglecting K, one would obtain the same result if one introduced directly in the wave equation of the heavy particles an exchange energy $A(r)$

$$A(r) = \pm\frac{g^2}{16\pi^3\hbar c r^5} I(r),$$

the sign of $A(r)$ depending on the symmetry of ψ in respect to a and b. Introducing the values of $\hbar$, c and g, we obtain

$$|A(r)| \ll 10^{-85} r^{-5} \text{ erg}$$

Thus $A(r)$ is far too small to account for the known interaction of neutrons and protons at distances of the order of $r \sim 10^{-13}$ cm.

If the difference of masses of the neutron and of the proton is larger than the sum of the masses of an electron and a neutrino, the emission of light particles by a heavy particle may take place without violation of the conservation of energy. But again *the corresponding value of the exchange energy may* be shown to be far too small

$$|A(r)| < g\left(\frac{mc}{\hbar}\right)^3 \sim 10^{-18} \text{ erg}$$

Our negative result indicates that either the Fermi theory needs substantial modification (no simple one seems to alter the results materially), or that the origin of the forces between neutrons and protons does not lie, as would appear from the original suggestion of Heisenberg, in their transmutations, considered in detail by Fermi.

Interaction of Neutrons and Protons

As electrons and positrons are expelled in some reactions from nuclei, we can try to treat these *light* particles like the photons emitted by atoms. Then the interaction of *heavy* particles (protons, neutrons) can be considered as taking place *via* light particles described by the equations of a ψ-field in the same manner as electromagnetic, for example, Coulomb, interaction takes place through an electromagnetic field, or photons.

The *first* order effects are the expulsion (or absorption) of an electron, which case was treated recently by Fermi, or of a positron. We may remark that the application of Fermi's formalism to positron disintegration of light nuclei (which we get by changing the sign of the charge number and taking for the latter the appropriate value) gives results which fit, though not very accurately, the observed relation between the half-period and the maximum energy of the disintegration particle[1]. Though there seems to be a quantitative disagreement between Fermi's theory (applied to positrons) and positron disintegration, on the other hand the calculated values for K and Rb support Fermi's assumption of the existence of quadripole transitions of heavy particles, giving too big values for the half-periods in comparison with the usual dipole disintegrations. The exceptional position of K and Rb is in some way rather *anschaulich*. We may remark that the Sargent-Fermi rule, in contrast to the Geiger-Nuttall law, shows a less pronounced dependence on the charge number, so that for qualitative considerations even the wave functions of free particles can be used.

The *second* order effects give specially the probability of production of pairs, which is in the case of the ψ-field less effective than in the electromagnetic case, as the charge, e, is much bigger than Fermi's coefficient, g (the 'charge' for the ψ-field). The most important second order effect is the subsequent production and annihilation of an electron and positron, in the field of proton and neutron, which leads to the appearance of an interaction *exchange* energy (Heisenberg's *Austausch*) between proton and neutron, quite in the same way as Coulomb interaction can be conceived as arising from the birth and absorption of a photon in the case of two electrons Instead of e^2/r one gets here an interaction of the order g^2/chr^5, which is easily verified dimensionally The exact calculations were first carried out by Prof Ig Tamm, who also insisted on development of this method With $g \sim 10^{-50}$ (the computations were carried out by V Mamasichlisov), which value is required by the empirical data on heavy radioactive bodies we get an interaction energy of a million volts, not at a distance of 10^{-13} cm but only at $r \sim 10^{-15}$ cm, which is inadmissible We may ask about the value of r, which would give a *self interaction* energy of the order of the proper energy of a heavy particle This value is of the order 10^{-16} cm, which is that of the classical radius of a proton

The appearance of those small distances is very surprising and can be removed only by some quite new assumptions Fermi's characteristic coefficient g appears to be connected also with distances of this order of magnitude

Barium in Ancient Glass

THE recent interesting exhibition of Chinese glass and beads—the property of the Royal Ontario Museum, Toronto—at the Courtauld Institute (University of London) arranged by Prof Yetts, prompts us to put on record the results of some work we have done on ancient beads and the presence of barium in them

The more ancient of the specimens exhibited—for the most part beads—are derived from graves (likely to be known in future as the Han Chun graves) near the village of Chin Ts'un in Honan Careful consideration by Prof Pelliot of the circumstances of their discovery leads him to place the date of these graves, and therefore of the beads, in the second half of the third century B C In China in 1929, and later by correspondence, we were able to collect a number of beads so closely resembling those of Han Chün that they may well have come from that site, and may definitely be regarded as of the same period and make Struck by the weight of a number of these specimens, we proceeded to compare their specific gravity with beads of Mediterranean' origin, and when we found this generally higher a number of analyses were performed It is not now our purpose to discuss our conclusions, but simply to direct attention to the following results

	Specific gravity	Analysis	
Blue glass bead with white inlay (Fig 1)	3 57	SiO_2	41 9 per cent
		PbO	24 5 ,,
		BaO	19·2 ,,
		CaO	4 5 ,,
		Fe_2O_3 Al_2O_3	4 4 ,,
		Alkalis	4 5 approx
		CuO	trace
Glass ear ornament	3 5	Contains 10 per cent mixed calcium and barium oxide, of this an appreciable amount is barium oxide	

The ear ornament is of the type sometimes known as capstan bead', and there is good evidence for regarding it as of Han date (202 B C–A D 221)

In modern times barium glass was not made until about 1884, when it was one of the new glasses with a high refractive index and low dispersion put on the market by Messrs Schott of Jena, nor have we any knowledge of any ancient glass or bead containing barium

We do not suggest that the ancient Chinese used barium purposefully in their glass—no doubt it was present in the material from which the glass was made, we do, however, consider that its presence may in the future allow of the determination of origin of beads in certain doubtful cases, and thus have some value in questions of early culture contacts between West and East, indeed it was the study of these that led us to our discovery

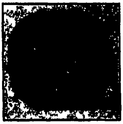

FIG 1 Bead of Han Chün type Natural size

It must not, however, be supposed that all Chinese glass of a high specific gravity, or all Han glazes, contain barium Dr F M Brewer, who has kindly examined by arc spectroscopy two specimens of Chinese glass and a piece of typical green Han glaze, reports that 'there was not in any of them any barium either as main or minor constituent' Of the two pieces of glass, one of T'ang age (A D 618–907) has specific gravity 2 5 the other—believed to be of this period—a specific gravity of more than 5

Rapid Growth-Rate and Diminishing Heterogony

A STUDY of relative growth in the pistol crab, *Alpheus dentipes*[1], has disclosed an interesting modification of the simple heterogony law, as expressed by the relation $y = bx^k$, where y and x are magnitudes of organ and body respectively, and b and k are constants k representing the coefficient of growth-partition between organ and body[2]

This relation may hold over very long periods—for chela weight in fiddler crabs, for example, apparently *during a two hundred fold increase in total weight*[3] The principle, however, may be modified in various ways One modification in particular may be mentioned here, namely, that found in the mandibles of Lucanidæ Here, in the upper part of the absolute size range, the actual values for organ size fall progressively further below the expected values This has been interpreted as due to growth occurring in a closed system, namely, the pupa · if the heterogonic organs are very large, they will not be able to complete their growth before the rest of the body has appropriated most of the reserves of nutrient material[3]

Something analogous appears to occur in the chelæ of *Alpheus* In males (for brevity's sake the only sex considered here) between the smallest and largest classes of the size range 3–10 mm carapace length, the small (nipper) claw has a greater growth-partition coefficient than the much larger (crusher) claw ($k = 1$ 22 as against 1 19)[1,4] When all the class means are considered, however, the log-log curve, instead of being a straight line, is concave downwards This is best shown when the square root of the two most rapidly growing dimensions—width and thickness (depth)—is used as a measure of chela magnitude (Fig 1) This applies both to crusher and to nipper claws, but is both more pronounced and of earlier onset in the crusher The *k* values for equivalent growth periods are shown in Table 1

TABLE I Growth of chelae in ♂ *Alpheus dentipes*

Period (classes)	Growth coefficient (*k*)	
	crusher	nipper
I II	1 99	1 34
II III	1 24	1 42
III V	1 10	1·49
V VII	1·09	1 10
VII IX	0 47	0 59

The interpretation would appear to be as follows — The growth coefficient of the crusher in very small males, outside the range of the table must be extremely high (well over 2) to produce the large relative size found at 3 mm carapace length The high rate proves physiologically impossible to maintain as the bulk of the crusher increases, and the growth coefficient therefore falls progressively The nipper has only a moderate heterogony (*k* never over 1 5), which it maintains (and indeed appears to increase slightly) up to a quite large body size then it too shows a decrease

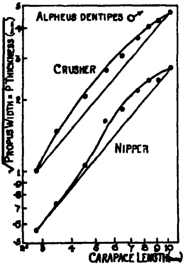

FIG 1 Double logarithmic plot of the chelae of ♂ *Alpheus* against carapace length

It must be left undecided whether the temporary increase of the nipper's relative growth just noted is associated with sexual maturity, and whether the very rapid decrease in the growth rate of both claws after class VII is a post maturity phenomenon, as seen in the secondary sex characters of *Gammarus*[4] What appears clear is the *diminishing heterogony* of the crusher, visible from carapace length 3–8 mm and deducible at earlier stages, and this would appear to be the direct outcome of an initial excessively high growth rate The phenomenon would be comparable to the diminution in total growth consequent on increased absolute size as noted by Hesse in various animals without a blood system[5]

While on the subject of heterogony, a further point may be noted The terms *positive* and *negative heterogony* originally employed[3] to denote relative growth with *k* values above and below 1 0, have proved in some ways misleading as suggesting that antagonistic processes are dominant in the two cases The alternative terms *hypergony* and *hypogony* are proposed accordingly, indicating that what is being considered is the level of an organ's growth intensity relative to that of the body as a whole

The Helmholtz Resonance Theory of Hearing

In a communication to NATURE of April 21 p 614, Messrs Hallpike and Rawdon Smith produce evidence of differential sensitivity of different parts of the cochlea to notes of different frequency, which they describe as favouring the resonance theory of hearing They use the expression 'differentially tuned" which I suggest assumes more than is justified by the evidence

There is one feature which the resonance theory does not explain, and that is that the human hearer cannot name the harmonics entering into the compound tone unless those harmonics are made loud enough to cause actual reversal of the primary wave I recall Prof Silvanus Thompson directing attention to this in 1898, at which time I demonstrated for him at a conversazione of the Royal Society a model illustrating an alternative theory of hearing due to Dr Max Meyer The following is Thompson s note on the Meyer apparatus

According to Max Meyer the ear does not act as a resonator and the perception of the individual tones of a compound sound does not depend on the fibres of corti acting as resonators His view is that disturbances communicated by the stapes to the inner ear travel up the basilar membrane to distances dependent on amplitude and damping, and that the perception of tone depends upon the number of times per second that the direction of such motion is changed The model does not profess to exhibit the mechanism of the ear, but to show, by the number of times that certain lamps light up in a single period, that a mechanism which is sensitive to changes of direction of motion can act as an analyzer of compound periodic motions

The Meyer apparatus depended upon a loose coupling between a series of parts Dr Meyer did not claim to have discovered a corresponding structure in the cochlea The action of the Meyer apparatus was consistent with the above stated peculiarity of human hearing as well as with differential sensitivity of different parts of the cochlea and suggests a closer examination of the process and mechanism of travel of sound throughout the length of the cochlea

Nuclear Structure, γ-Ray Fission, and the Expanding Universe

PROF G W TODD[1] has put forward evidence against the suggestion that the positron is a constituent of the nucleus He states that for a definite atomic mass P, and a definite atomic number Z, the arrangement of α particles, neutrons, etc , in the atomic nucleus should be such as to give a unique structure for the nucleus Allowing the possibility of positrons but excluding the possibility of unattached electrons Todd constructed the following arrangement for the unique structure

$$\tfrac{1}{2}(Z - K)\ \alpha \text{ particles} + (P - 2Z + 2K) \text{ neutrons} + K \text{ positrons}$$

where $K = 0$ or 1 whichever makes $\tfrac{1}{2}(Z - K)$ an integer

For reference Todd s table for α and β ray transformations from uranium is given below (n stands for neutron and p for positron)

	Nucleus			Radiation
UI	46	+ 54n	+ 0p	
↓ UX	45	54	0	α
↓ UX$_2$	45	54	1	β
↓ UII	46	50	0	β
↓ Io	45	50	0	α

We find as UX$_1$ is transformed into UX$_2$ the following change takes place $0 \rightarrow 1p + 1\beta$ the positron remaining in the nucleus

Prof Todd asks Where do the electron and positron come from in this change ? If we accept the suggestion that a γ ray of sufficient energy may undergo fission into a positron and an electron in the strong electric field of the nucleus the apparent anomaly may be explained Now β ray emission was preceded by *emission of α particles* and *if some* α particles without getting out of the nucleus just shift their positions from higher energy levels to lower levels there would be emission of energy which would appear as γ ray radiation Some of the γ rays would very likely undergo fission into positrons and electrons within the nucleus The positron of the γ ray would attach itself to the nucleus and thus increase the atomic number by one and the β particle would escape

We find that as UX$_2$ is transformed into UII, a new α particle is created according to the transformation

$$4n + 1p \rightarrow 1\alpha + 1\beta,$$

the α particle remaining in the nucleus This transformation can also be explained by assuming that an α particle is an aggregate of four neutrons and two positrons, and also a positron and an electron were created out of a γ ray and the two positrons combined with the four neutrons to form the α particle It may be pointed out that a β ray transformation is usually accompanied by γ ray radiation The binding energy of a proton is presumably great, and so its dissociation into its constituent parts can not be spontaneous Naturally we come across a comparatively small number of neutrons and positrons

Dirac has suggested the possibility of a negative proton[2] A plausible hypothesis may be formulated according to which super γ rays or cosmic ray photons may also undergo fission into positive and negative protons A proton has the energy of $9 4 \times 10^8$ electron volts, and a cosmic ray photon may have the energy of the order 10^{11} electron volts

The breaking up of a photon into an electron and a positron or into a positive proton and a negative proton may be helpful in explaining why our universe started expanding from the Einstein universe We know that, mass for mass, matter exerts less gravitational attraction than radiation So the conversion of radiation into matter will lessen the gravitational factor Therefore if by some method the photon breaks up into two material particles, the Einstein universe will start expanding Possibly radiation, as well as the fundamental material particles, already existed in the Einstein universe Some of the photons broke up into constituent particles in the electric field of already existing charged particles and thereby started expansion

I also feel that the final end of the universe as predicted by Sir James Jeans, due to all matter ultimately dissolving away into radiation, may not happen as materialisation of radiation is possible, and electrons, positrons, positive protons and negative protons can be created or re formed out of the photons It may also be mentioned here that Prof Tolman established the possibility of a universe in which reversible processes take place, without entropy reaching a maximum or free energy a minimum

Afterglow of Carbon Dioxide

IN a recent paper[1] it has been shown that carbon dioxide, when excited to luminescence by an electrical discharge in a vacuum tube, possesses a blue violet afterglow having a spectrum similar to that obtained by burning carbon monoxide in air or oxygen The spectrum has now, on the suggestion of Prof A Fowler been produced from a modified source which is brighter than the afterglow in the gas at low pressure

A powerful uncondensed spark from an 18 in induction coil was passed between water cooled aluminium electrodes in a spherical bulb of about three litres volume , the spark was horizontal , the distance between the electrodes was variable, but the best results were obtained with a separation of about five centimetres The bulb was filled with carbon dioxide at a pressure of about a quarter of an atmosphere It was observed that the spark, which resembled an arc, was accompanied by a blue glow above it This glow persisted for a fraction of a second after the cutting off of the discharge

The spectrum of this glow has been examined between 6000 A and 2900 A , and found to be similar to the spectrum of the afterglow at low pressure and to that of the carbon monoxide flame The water vapour band at 3064 A , which was such a prominent feature of the spectrum of the afterglow, was however, not observed when the gas was carefully dried Even when the gas was slightly wet showing the water vapour band in the spectrum of the exciting spark, this band was still quite weak in the spectrum of the glow above the spark This supports the view that the presence of water is not essential to the occurrence of the afterglow The spectrum of the exciting spark consisted of the third positive and Angström bands of carbon monoxide, the afterglow bands were also present on the spectrograms of the spark, but this does not necessarily imply that they were present in the exciting spark as the glow was also included in these spectrograms No lines of atoms other than those of aluminium from the electrodes, were observed in the region examined

The effect of variation of the pressure of the gas has been studied At a pressure of about half an atmosphere the glow was brighter but the spectrum included a considerable amount of continuous background resembling the carbon monoxide flame as usually obtained At a pressure of about 100 mm the glow was much fainter and the spectrum more nearly resembled that of the afterglow in a vacuum tube, showing a well marked band structure and being comparatively free from continuum

Absorption Spectrum of Mercuric Sulphide

WE experimented with the absorption spectrum of gaseous mercuric sulphide The substance was introduced into a quartz absorption tube which could be heated to about 400° C by electrical means steps being taken to prevent condensation on the plane quartz ends The copper and aluminium under water sparks were used as sources of continuous radiation The sulphide seems to decompose very readily and we obtained evidence only of the presence of Hg vapour by the resonance line 2536 A and of S_2 and, at high pressures, of S_8 by the sulphur bands, which we identified without much difficulty At higher pressures the overlying continuum becomes very prominent, and the banded structure disappears, as is usually the case with a gas under such conditions

We would not have published these results were it not for the fact that recently Sen Gupta[1] claims to have shown that mercuric sulphide dissociates in three regions of continuous absorption into Hg ($^1S_0$) and S (^3P) S ($^1D_2$) S ($^1S_0$) respectively We re-examined our plates in the hope of verifying this, and can only say that the separation of these distinct absorptions from the sulphur continuum must be one of very great difficulty In fact, we cannot be sure if the first two regions are not entirely due to sulphur, which has two maxima, 4000 A in the S_8 region and 2670 A in the S_2 region Our absorption spectra for HgS followed very closely the spectra published for sulphur at high pressures by Graham[2]

The heat of dissociation of HgS has been calculated to be 60–70 kcal This makes the reaction $2HgS = Hg + Hg + S_2$ endothermic so that the dissociation will be greater at the higher temperatures and pressures, and there will be a relatively larger concentration of S_2 compared with HgS Consequently the interference effect due to S_2 will become more and more pronounced as the temperature is raised and it seems useless to try to increase the concentration of HgS in this way

The whole question of the existence of an absorption spectrum of HgS would seem to centre round the electronic state of the molecule If it is a $^1\Sigma$ ground state it would not dissociate into Hg ($^1S_0$) and S (^3P) as these atomic states do not combine to give a singlet state (Wigner and Witmer, Herzberg, etc) Whether the first excited state dissociates in this way will depend on the probability of the intercombination, so that the absorption spectrum of HgS in the necessary region may only be very slight and perhaps immeasurable

It is noteworthy that V and C Meyer[3] found HgS to have a vapour density (compared with air) of 5 39 The vapour density of $Hg + Hg + S_2$ is not much different from this namely 5 35

Intranuclear Spindle Formation and Mitosis in *Artemia salina*

CYTOLOGICAL studies on *Artemia* have brought out some new facts about the structure of the spindle and the morphology of the meiotic and mitotic division in this form which agree only in part with previous hypotheses (For a recent discussion of these see Schrader[1]) To what extent these data bear upon the general understanding of the problem of mitotic division will be considered elsewhere in more detail

In *Artemia* the spindle, both in meiotic and cleavage divisions is formed exclusively from nuclear material It arises as two half spindles from the poles of the nucleus inside the nuclear membrane which remains intact up to early metaphase (Fig 1 *a*) Its formation is accompanied by a steady loss of nuclear volume indicating that the process involves a great reduction in the fluid content of the nucleus During metaphase the nuclear membrane rapidly disappears

There is a distinct structural difference between the polar fibres and the spindle fibres The metaphase spindle is barrel shaped and in early cleavage divisions stands out sharply against the polar fibres of the big centrospheres It has a very similar form in the metaphase of the meiotic divisions where there are no formed centrosomes or centrospheres and in the late cleavage divisions, where these are only weakly developed (Fig 1 *b*)

In the spindle two components can be distinguished (1) relatively rigid fibres immersed in (2) a less viscous matrix During anaphase, the chromosomes move to the two poles leaving a much lighter central space (Fig 1 *b*) The fibres found in this central space between the two sets of chromosomes would seem at first sight to correspond to Schrader's interzonal fibres, but in this case they appear to be identical with one component of the metaphase spindle, namely, the rigid fibres

It may be suggested that during anaphase the chromosomes are moving as on tracks—or possibly within tubes as suggested by Schrader—along these rigid fibres The anaphase spindle is more cylindrical and less compact than the metaphase spindle One can see the underlying yolk granules through it whereas this is impossible in metaphase These facts suggest that there is a streaming of the interfibrillar substance—the matrix between the rigid fibres—towards the centrospheres and that the movement of the chromosomes is somehow connected with the currents thus produced

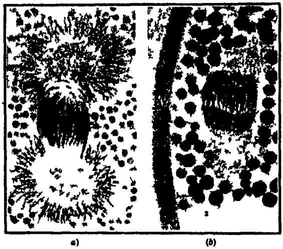

FIG 1 (a) Early metaphase of the first cleavage division in a diploid parthenogenetic *Artemia* Intranuclear formation of the spindle × 590
(b) Anaphase of a late cleavage division in a polyploid parthenogenetic *Artemia* The centrospheres are here weakly developed as compared with the first cleavage Note that the polar regions are denser than the space between the two sets of chromosomes × 1 320

As soon as the chromosomes reach the ends of the spindle they lose their regular arrangement in planes and form more or less spherical clumps This is consistent with the assumption that the rigid fibres act as supporting structures and at the same time separate the chromosomes from each other The spindle remnant is always to be seen in telophase It is noteworthy that in the first cleavage division the chromosomes after leaving the spindle and assuming the clumped telophase arrangement may continue their movement towards the centrospheres

The Discovery of *Acanthinula harpa*, Say, in Central Siberia

IN the course of a study of the molluscan fauna of Siberia carried out under the auspices of the Smithsonian Institution during 1932 and 1933 a point has come to light which appears to merit special notice This concerns the discovery of the gastropod mollusc *Acanthinula harpa* Say in central Siberia This species has long been known to occur in Europe North America and the eastern fringe of Asia (Kamchatka etc) and its apparent absence from the central part of Siberia led Dall[1] to believe that migration into that territory had been delayed by a transgression of the sea or of glacial ice over at least a part of this region

The collection of *A harpa* in three different localities in the central part of this region namely near the River Ket (to the north of Tomsk) at a point situated two hundred and ten kilometres above the River Ob on the western shore of Lake Baikal in the vicinity of the village of Listvinichnoye and on the eastern shore of the same lake twenty five kilometres north east of the mouth of the River Selenga indicates that this is a circumboreal species and obviates the need on these grounds of the hypothesis noted above

Activities of Life and the Second Law of Thermodynamics

I AM at one with Profs Donnan and Guggenheim in hoping that this discussion will end soon but ask leave to explain why I think that their supposed paradox[1] is merely a third mare's nest

It is a well known and indeed obvious fact that entropy has different values according as it is measured with reference to atoms or molecules or other units Profs Donnan and Guggenheim have re-discovered this hail it as a paradox and claim that because this paradox exists my arguments must be unsound As well might they rediscover the paradox that temperature has different values according as it is measured on the Centigrade and Fahrenheit scale and try to use this as ammunition against anyone who mentions temperature

Research Items

Cannibalism in North-West America A study of mortuary and sacrificial anthropophagy on the north west coast of America and its origins has recently been published by Dr William Christie MacLeod (*J Soc Américanistes* N S , 25, fasc 2) Among the Kwakiutl there is a group of dances either cannibalistic or related to the cannibal dance A youth who in his quest for a vision meets the great cannibal spirit or any of the cannibal s attendants, acquires the dance, derivable from the spirit An analysis of the elements of this belief and of the lore connected with cannibalism indicates that the dance was diffused from the northern Kwakiutl as the centre It is evident, however, that the dance consists of a number of elements which were diffused separately and have been only imperfectly integrated among the Kwakiutl There are three elements which have a different history and can be traced Of these corpse eating by the relatives of the deceased was an old culture element of the entire west coast of North America and the northern plateau It was linked with the custom of bone carrying by the widow and the custom of smearing with exudations of the corpse, or its blood, as an equivalent of eating Among the Kwakiutl the custom of mortuary anthropophagy probably represents a survival from the culture of a pre Kwakiutl tribe The second element the custom of biting bits of flesh from fellow tribesmen at ceremonials is of inner American introduction and probably is a by product of hook swinging In inner North America the rite is self sacrifice of bits of skin Thirdly, non anthropophagous sacrifice of captives in war was diffused to the west coast from inner America, and afterwards, through the Kwakiutl, anthropophagous practice followed in connexion with the rite of hook swinging The strips of flesh technique in sacrifice of both Maidu and Kwakiutl is of inner American origin and still survives among the northern Plains and Woodlands Indians

Rabbit Fur Production As a rule rabbit fur has been worn in garments only when no other could be afforded, objections to it being that the hair soon becomes worn and shabby in appearance and, curiously enough that it is cheap In recent years however, much has been done by careful selection and breeding to improve the lasting quality of rabbit fur, and to furnish a wide range of desirable colourings As a result, it is now possible to produce natural undyed and untrimmed furs which closely resemble pelts from the rarer and more expensive fur bearing animals Much of the progress has been due to the discovery in 1919 of a mutation, later known as castorrex, in which a short, dense, under fur with almost a velvety texture is the predominant coat, the guard hairs of the outer fur being reduced to insignificance The rex-coat character acts as a Mendelian recessive, and breeders armed with a knowledge of the behaviour of this character in crossing have to their hand an invaluable aid in producing coat varieties new in colour and texture The Ministry of Agriculture and Fisheries has published a Bulletin (No 73) on 'Rex furred Rabbits" (London H M Stationery Office 1*s*) which gives a description of experiments carried out by W King Wilson at the National Institute of Poultry Husbandry The pamphlet illustrated by eleven fine reproductions of colour photographs of stages shown in the first and second generations of hybrids resulting from a cross between normal furred lilac and castorrex, should be a useful guide to the breeder It would be interesting to know if these beautifully coloured natural furs stand exposure to light without fading

Hair Direction in Man and Apes Dr T D Stewart, physical anthropologist of the Smithsonian Institution has made a preliminary classification of the differences in hair growth directions over the whole body between man and the higher apes The comparisons are based upon 156 skins of gorillas, chimpanzees and orang outangs and upon young men stripped for physical examination There is much in common between the two groups, which possess a basic hair direction pattern from which each species has departed to some extent In man the pattern has become more modified than in any of the others, the most obvious human feature being the cow lick on the top of the head In the apes the head hair streams regularly backward from forehead to nape (like that of a modern well oiled youth !), and this direction is continued without break along the back where the hair streams downward from neck and shoulders It is in the back pattern of man that the most striking divergence appears for instead of showing a regular downward flow, the hair of each side converges towards the mid line Man has the most complex and most variable pattern, but the difference between man and any of the anthropoid apes is greater than that between any two of the apes

Whaling in the Dominion of New Zealand Capt Cook visited New Zealand in 1770 1773 and 1774 and he was the first to report whales in those seas In Discovery ' Reports, 7 239 252, 1933, Mr F D Ommanney gives a brief outline of the history of the whaling industry in New Zealand and a sketch of the small industry as it exists to day One of the first attempts at large scale whaling in the vicinity of New Zealand was made in 1791 by a fleet of whalers which had arrived in Australasian waters through having brought convicts and stores to Australia It met with no success because although whales were abundant enough the weather proved too bad for profitable fishing Seven years later, however, Sperm whaling was being actively carried on in New Zealand waters, mainly by British and American ships the chief bases of which were situated at the northern end of South Island By the end of the third decade of the nineteenth century the population of Sperm whales in those waters had become seriously depleted As a result of this diminution in the number of Sperm whales and also because of an increasing demand for Right whale oil and whalebone a Right whale industry arose in 1830 and quickly eclipsed the Sperm whale fishery in importance Ten years afterwards this fishery, too began to decline owing to diminution of the whale population by ruthless overfishing, and by 1892 the New Zealand whaling industry had sunk to insignificance Several recent attempts to revive it have been disastrously unsuccessful At present there are only two whaling stations operating on a small scale in New Zealand —one at Whangamumu and one at Torry Channel Queen Charlotte Sound

Fæcal Pellets from Marine Deposits. Mr Hilary B Moore has already made several studies of the fæcal pellets of various marine animals, finding in them good diagnostic characters for certain species In vol 7 of the 'Discovery" reports, 1933, he describes a type of pellet occurring frequently in the plankton at some stations which he recognises as agreeing in form with those of euphausiids found in the Clyde He believes them to belong almost certainly to *Euphausia superba* which is very abundant in the plankton at the same stations They were not found in the bottom deposits, probably because they break down quickly, as was observed in the Clyde, where they were seen at the extreme surface of the mud but not below The pellets from the bottom deposits are not so easily identified although they can be separated into two classes One appears to be from a mollusc, possibly *Nucula*, and includes many diatoms, the other, which is much more abundant, is of a kind the distribution of which is world wide, occurring in recent deposits in depths from 0 to more than 2 000 m and in conditions varying from almost fresh to salt water, also in certain fossil deposits These pellets are ovoid and composed of the same mud in which they are found and are probably of animal origin The author is inclined to attribute them to polychæte worms or to molluscs The former seems very likely as he has found similar pellets in the Clyde which come definitely from Maldanid worms

Ascidiacea of the North Sea The section on Ascidiacea by J Huus, in 'Die Tierwelt der Nord und Ostsee (Lief 25, Teil xiia$_2$. 1933 Leipzig Akademische Verlagsgesellschaft m b H) opens with a useful account in about 10 pages of the external features and internal anatomy The author recommends weak acetic acid as a narcotising agent for these animals which, unless narcotised, contract strongly on preservation The systematic section, with its diagnoses and key, is followed by a list showing the distribution of the 55 species considered An excellent summary of the physiology of Ascidiacea is given, attention is directed to glands of unknown function, such as the pylorus glands and the neural gland The author notes that the latter is known to develop from a part of the larval brain, that Julin pointed out its homology with the hypophysis, and that Butscher found its extract has the specific action of posterior lobe hormone The development is briefly considered, a first key to the larval forms of the area is provided, and due attention is given to the process of budding The section concludes with a list of the animals which live symbiotically with or parasitic within or upon, Ascidiacea

Discoloration in Preserved Latex. A very valuable discussion of this subject by Edgar Rhodes and K C Sekar will be found in the *Journal of the Rubber Research Institute of Malaya* of March 1934 Extending earlier observations by de Vries, it can be shown that such discoloration can usually be traced to the presence of soluble iron, and the presence of the iron may often be associated with acid production due to fermentative changes with the consequent solution of iron from metal containers This soluble iron then may react with hydrogen sulphide or other soluble sulphide, the sulphide being produced as a rule by the gradual hydrolysis of the protein material in the latex, a process taking place more readily under alkaline conditions, which may occur as the latex before shipping is usually treated with ammonia Thus acid production following collection, associated with iron containers, and then sulphide production following ammoniation before shipping, are accessory factors in discoloration The discussion of this problem may enable grower and shipper to combine to reduce the discoloration in the latex which otherwise makes it unsuitable for many of the new processes in which rubber latex is now being utilised

Vegetation of Prairies The April number of *Ecological Monographs* (4, No 2, 109–295, 1934) is a general account of prairie vegetation by J E Weaver and T J Fitzpatrick The areas which prairie occupies are characterised by cold winters and hot summers, with a growing season of about seven months, during which there is a fairly even distribution of rainfall amounting to 19–20 inches The total annual rainfall is from twenty five inches in the north west increasing to thirty six inches in the south east Despite the high temperatures and considerable wind, water is almost always present below six inches and this is rendered available by well branched root systems which tend to form three underground strata The shallowest roots mostly extend to a depth of about a foot, but the unleached deep organic soil, which is well aerated, permits the development of deeply penetrating root systems, some of which even extend to seventeen feet below the surface Six types of prairie are distinguished by their floristic constitution, the most important being those dominated by *Andropogon scoparius* and *A furcatus* All the dominants and most of the other important species are perennials which reproduce mainly by vegetative means Most of the prairie areas are stated to have been mown annually for more than fifty years and this, together with the fires and grazing to which they have been subject since prehistoric times, have checked the tendency shown by the more feral areas to form communities of a few dominants only At the contacts with woodland and forest, colonisation by shrubby species occurs, though their growth is checked by the factors just mentioned *Rhus glabra* and *Symphoricarpus vulgaris*, both of which spread by vegetative means, are important pioneers in such suppressed scrub, but it is suggested that even if not checked by mowing and fire, chaparral and woodland could not greatly extend the areas which they at present occupy In this connexion it must, however, be borne in mind that the authors themselves emphasise that the prairies are associated with a wide range of conditions both as to soil and topography A considerable part of the text of this monograph consists of notes, of varying merit, upon the constituent species

Blight Diseases of Leguminous Plants. A study of various fungi which produce disease on legume crops in India has recently been published (*Trans Brit Mycol Soc*, 18, Part 4, 276–301, April 1934. "A Comparative Study of the Fungi associated with Blight Diseases of certain cultivated Leguminous Plants" ,by Dr A Sattar) Nine species or forms of fungi which cause foot rots of pea, gram, lentil and vetch are described The symptoms of each fungus are given for its respective host plants, and cultural characters of the parasites have been determined *Ascochyta pisi*, a fungus which is well known in England as a parasite of the garden pea, was found to have physiological forms on vetch and lentil *Phyllosticta Rabiei* also has a close relation with its host (gram), whilst *Mycosphærella pinodes* and *Ascochyta pinodella* are not so specialised. The last two organisms cause very severe foot-rot. Considerable discussion of the results of the experiments as they relate to taxonomy appears in the paper, and it is suggested that *P. Rabiei* should be more correctly named *A. Rabiei*.

Earthquakes in Bulgaria. With the exception of Greece and Italy, no European country is more frequently disturbed by violent earthquakes than Bulgaria. It is therefore fortunate that it should possess an efficient seismological service, the work done by which during the last forty years is described in an interesting paper by M. Kiro P. Kiroff, the director of the Central Meteorological Institute (*Matér. pour l'Étude des Calam.*, No. 32, 341–348, 1933). The service was founded by M. Spass Vatzoff, the director at that time. A table is given of the number of earthquake days during each month of 1892–1931. From this it appears that on an average there were 44·4 days every year on which earthquakes occurred, the highest yearly numbers (213 and 134) being those for 1904 and 1928, including the after-shocks of the destructive earthquakes in April of each year. During the forty years, there were eight earthquakes of destructive intensity with epicentres either in Bulgaria or close to its borders.

Gravity Work in East Africa. The annual report 1934, of the Committee for Geodesy and Geophysics at Cambridge gives a short account of the notable work done by Dr. and Mrs. Bullard in the recent Cambridge Gravity Expedition to East Africa. Dr. Bullard was in Africa from last November until early April this year, and during that period made gravity observations at 57 stations, several of which were visited twice and some three times. The tour extended from Nairobi through the west and north-west part of Kenya, Uganda, the southern Sudan, part of the Belgian Congo to the west of the Rift Valley, and back to Nairobi through Uganda. Dr. Bullard then proceeded to Mombasa through Tanganyika, and from Mombasa by coast to Cape Town, making shore observations at Dar es Salaam and Cape Town. The photographic records of the observations, which were made with invar pendulums by Dr. Bullard's comparison method, were sent to Cambridge weekly by air mail. The reductions are not yet complete, but it appears clear that the accuracy obtained is of a high order. Dr. Bullard also made valuable magnetic observations on his tour, using instruments lent by the Ordnance Survey and the Carnegie Institution of Washington. These observations included 159 of declination, 58 of horizontal force and 18 of inclination.

Insulators. The mechanism by means of which flow of electricity takes place in materials which are almost insulators is still obscure, but the publication of Prof. Joffé's address to the International Congress on Physical Chemistry on the subject, and the discussion which followed, will do much towards clearing away the obscurity (Pp. 35. Paris: Hermann et Cie, 10 francs.) In the case of an insulating crystal, Prof. Joffé considers that the thermal oscillations are sufficient to detach an ion occasionally from its normal position in the space lattice of the crystal, and that the absence of the ion from that position and its presence elsewhere produce deformations of the space lattice which are propagated by the electric field applied to the crystal, but gradually disappear owing to the thermal movements replacing the ions. When this process takes place slowly, the resistance of the crystal may be very small. Prof. Joffé believes that in no case has the replacing ion to overcome an energy barrier. He considers that the retention of conductivity by a crystal when its temperature is suddenly reduced points to the fact that in a crystal some ions exist displaced from their normal positions, and that their number increases with temperature and with the passage of light or X-rays. The pamphlet is to be followed by one on conduction by electron movements.

Strychnine and Brucine. The constitution of these two alkaloids has proved a very difficult problem to the organic chemist, and further communications to the *Journal of the Chemical Society* (May 1934) by Prof. R. Robinson and collaborators (the first bearing the name of the late Prof. W. H. Perkin) bring the number of parts of the work up to twenty-nine. The problem is not yet fully solved but considerable progress has been made. An important contribution is the progress made in the Hofmann degradation of the molecules, which has hitherto proved very intractable. It had been recognised that both strychnine and *neo*strychnine are of the allylamine type, and that Hofmann eliminations in the series of the dihydro bases in which the allylamine structure is no longer present might be a promising line of investigation. This is now shown to be the case. A very interesting and unexpected reaction was also discovered in the reduction of a new base, leading ultimately to a new isomeride of dihydrostrychnidine. The previous suggestion that strychnidone obtained by the oxidation of *neo*strychnidine is a keto-amide has also been confirmed. A method of oxidation of *neo*strychnine derivatives by perbenzoic acid is described. The papers contain a number of important observations which cannot be summarised adequately without reference to other previous ones in the series, and it is clear that the solution of the problem of the constitution of strychnine is considerably advanced by the work now recorded.

First Dissociation Constant of Phosphoric Acid. Phosphoric acid is a comparatively weak acid and has the peculiarity that the acid function of its three hydrogen atoms varies greatly. The dissociation constants are important in physiology and the values for the first dissociation constant $(H_3PO_4 \rightleftharpoons H^+ + H_2PO_4^-)$ available are not in very good agreement. L. F. Nims (*J. Amer. Chem. Soc.*, May) has determined this constant, expressed in terms of activities, over the temperature range 0°–50°, from electromotive force measurements of the cells

$$H_2/HCl(m_1),\ KH_2PO_4\ (m_2)/AgCl/Ag,$$

without liquid junctions. The limiting Debye-Huckel equation $\log \gamma = -A\sqrt{\mu}$ was used for the activity coefficient of HCl, the ionic strength μ being expressed by $m_1 + m_H$, in which m_H is the apparent hydrogen ion molality from the electromotive force equation. The values of $pK_1 = -\log K_1$, K_1 being the first dissociation constant of phosphoric acid, were found by graphical extrapolation of very satisfactory lines. The equation $\log K_1 + 2·0304 = -5 \times 10^{-5}\ (t + 18°)^2$ was found, t being temperature centigrade. The values so obtained are in very good agreement with those found by conductivity at 18°, and by the quinhydrone electrode at 37·5°, by other experimenters.

Speeds of Chemical Reactions in Biological Processes

SEVERAL interesting points were raised at the discussion on June 14 at the Royal Society on methods of measuring and factors determining the speed of chemical reactions The discussion, which was opened by Prof A V Hill had as its main objective the exploration of methods suitable for attack on biological problems

Several of the difficulties in such work are now generally recognised, we must note, for example, that physical methods of attack are likely to prove more fruitful than chemical methods since there are few reagents that do not disturb in some manner the complicated series of reactions proceeding in living matter Again, in the chemical laboratory it is customary to restrict one's attention to reactions in solution which proceed at speeds conveniently measurable In biological systems it is the reactions which are predetermined and their velocities have to be measured Whilst a half life of some ten seconds after mixing the reactants is almost the limit of accurate measurement by the usual methods many biologically important reactions proceed much more rapidly Prof H Hartridge and Dr F J W Roughton showed how, by means of specially designed mixing chambers using liquids at high pressures and optical or electrical examination of the mixed liquids in flow reaction velocities having a half life of as small as 1/4,000 sec could be determined An extension of this method by Mr G Millikan involving a photoelectric cell permits of a greater degree of sensitivity and the elaboration of a micromethod

The modern extension of the kinetic theory of reactions to complicated molecules is bringing into prominence the importance of what is termed the steric factor, thus a very large molecule undergoing reaction at one of its constituent groups may be regarded as only potentially active over a relatively small fraction of its total area These steric factors may play an important part in biological reactions in two somewhat dissimilar fields We find that steric factors already intrude in such comparatively simple homogeneous reactions as the addition of hydrogen to, say, the double bond in propylene, and may anticipate that there is indeed a very large steric factor in the reactions of, say, oxygen with hæmoglobin It will be interesting to examine from this point of view the results obtained from measurement of the reactions of the less common and extremely large molecule biological pigments, the molecular weights of which as determined by the super centrifuge, run into the millions

Again numerous biological processes occur at phase boundaries or interfaces, and such reactions possess several interesting peculiarities which are well worth extended investigation Prof H Freundlich pointed out that whilst surface catalysis is a relatively common phenomenon, there are cases in which retardation of a chemical reaction can be brought about by a simple extension of surface, he cited as an example the reaction

$$\mathrm{H_2C(Br)\ CH_2\ NH_2 \underset{HBr}{\overset{NaOH}{\rightleftharpoons}} \begin{matrix}CH_2\\ |\\ CH_2\end{matrix}\!>NH + HBr,}$$

which is retarded by charcoal in alkaline solution It is difficult to decide whether the adsorbed molecules are firmly adsorbed and so removed from the solution, to which the reaction is confined, or whether reaction is proceeding both in solution and in the adsorbed layer, but in the latter, which may be regarded as an organic medium, the reaction proceeds much more slowly

In the case of monolayers at fluid interfaces, it is a simple matter to contract or extend the area per molecule by means of a Langmuir trough, and it is possible to examine reaction rates in monolayers by determination of the rate of change in the phase boundary potential As has been shown in the present writer's laboratory at Cambridge the velocity constants of numerous reactions in monolayers may be altered to a marked extent by extension or contraction of the film Thus there is remarkable decrease in the rate of oxidation (by dilute permanganate solution) of the double bonds in a monolayer of oleic acid on suitable compression of the film, or, to suggest a possible analogy to stretched muscle, there is an increased rate of oxidation on extension of the film The action of enzymes on monolayers of reactants for example, lecithinase on films of lecithin is similarly sensitive to an alteration in the molecular concentration or steric factor, which in these cases can be controlled at will

In addition to the steric factor the energy of activation plays a dominant part in determining the rate of chemical action, and it is still a matter of speculation as to the accuracy of assessing the magnitudes of the individual energies of activation in the complex chain of biochemical processes Prof M Polanyi pointed out that many ionic reactions in solution require energies of activation and that unsuspected reactions may indeed be taking place. He cited as a typical example the racemisation of optically active halides by negative ions, which reaction may be written

$$X^1 + \begin{matrix}R_1\\ R_2\\ R_3\end{matrix}\!>CY \rightarrow XC\!<\!\begin{matrix}R_1\\ R_2\\ R_3\end{matrix} + Y^1$$

Where X^1 and Y^1 are identical, that is, $X^1 = Y^1$, racemisation can take place without the occurrence of any apparent chemical reaction although in fact an ion exchange does take place

Both in chemistry and in physics, a vast number of relative speeds of complicated processes are found to be exponentially temperature dependent, and the mechanisms of these processes are always interpreted on an atomistic hypothesis Prof J B S Haldane pointed out that either this inference may not be universally legitimate or a materialistic concept must be given to such curious processes as the subjective measurement of time, for here the logarithm of the relative speed of counting is found to vary inversely as the absolute temperature of the counter, giving a computed energy of activation of 24,000 calories The speed of bimolecular gas reactions is accelerated by increase of pressure, and the recent experiments carried out by the Imperial Chemical Industries at Northwich have revealed a surprising increase in velocity of many chemical reactions in the liquid phase when suitably high pressures are employed Prof Max Cmcatel directed attention to this as a possible method of effecting a sudden change in the environment of a living system and examining the effect of this change on the various reactions taking place

Some brief references were also made to the importance of finding a really accurate method for measuring the true permeability rates of extremely thin membranes Theoretical investigations in this field have already been made by Prof A V Hill and Dr F J W Roughton indicated how the streaming method could be made applicable to blood cells thus permitting an examination of the true rates of ingress and egress both of non electrolytes and of ions

ERIC K RIDEAL

Water Supply

It is natural and appropriate that the paramount topic of the drought should find a prominent place in the presidential address of Mr Councillor Thomas Paris at the annual meeting of the British Waterworks Association (Incorp) at Edinburgh on June 27 Much of what he had to say respecting the pernicious effects of a shortage of water has been a matter of common experience but he made the pertinent observation that many of the failures in supply can be traced to procrastination and lack of courage in promoting water schemes This was more particularly in reference to rural areas where he emphasised the importance of an abundant supply of wholesome water is hardly to be over estimated since insufficient or impure water in those areas has wide reaching effects on public health through milk and foodstuffs produced for general consumption He alluded to the frequent lack of storage facilities and urged all councils regional urban and rural to take action in the direction of increasing their storage and where necessary constructing new waterworks Another of his points was river pollution which he contended in the national interest must cease He instanced the case of Edinburgh where a few years ago there was a turbid stream flowing through the city offensive to eye and nostril The action taken by civic authority has resulted in the transformation of a public nuisance and a menace to health into a fished water He is opposed to the formation of a national water grid alleging that the argument for such a grid so far as Scotland is concerned is without foundation The question in his view is not one of water shortage but rather of storage and distribution

Among the papers contributed to the Conference was one of a particularly timely character on the Consumption Misuse and Waste of Water Mr John Bowman the author of the paper, directed attention to the striking difference in the quantities of water supplied per head per day by various authorities He gave a list of 114 authorities in England each supplying a population of more than 50 000 in which the consumption ranged from 13 00 to 73 45 gallons per head per day Another list showed that among 27 water authorities in Scotland the consumption ranged from 34 to 92 gallons per head per day Commenting on the subject of undue consumption which might be defined as the use of more water than is necessary he said a person living in a country where water is scarce may find it possible to perform all his ablutions with one gallon of water per day and half as much again for culinary and drinking purposes In civilised countries it would appear that at least from 4 to 6 gallons per head must be allowed where there is no water used for baths or water closets Where water is used in addition for the supply of water closets it would appear that the lowest figure is about 10 gallons per head Much depends on the class of property Houses of the residential class have a higher *per capita* consumption than small tenements

Mr Bowman went on to ask the question What is to be regarded as the future requirements for ordinary domestic consumption ? He gave it as his opinion that within the next twenty years at least 20 gallons per head per day would have to be provided for the increased use of baths The requirements per head per day would then be in the region of 50 gallons Perhaps forty years from now a consumption of 80 gallons might be considered possible In American towns 80 gallons per head is looked upon as a normal consumption Dealing with the question of waste which he attributed largely to defective fittings he stated that a good deal of it might be eliminated by the installation of heavy service piping and good fittings Useful work he thought might be done in educating the householder in the avoidance of waste due to faulty fittings and in getting him to see that taps were left properly turned off and to use water without undue consumption

Fish Preservation in Trawlers

With the introduction of steam driven vessels —somewhere about the year 1870—the great development of the present long distance deep sea trawling industry became possible But the industry s present greatness is not due to steam alone Had not the practice of stowing the catch in crushed ice been also introduced about the same time the bringing back of fish in a saleable condition from far distant grounds would have been impossible even for large and powerful steamers unaffected by the vagaries of wind propulsion

In recent years many experiments have been made in an endeavour to evolve and perfect a more satisfactory method of preserving fish at sea In spite of every effort towards improvement however the stowage of trawled fish in crushed ice is still the general practice notwithstanding its very serious limitations

The preservative effect of crushed ice is two fold By lowering the temperature of the fish tissues changes due to autolysis are slowed down This lowering of temperature also slows down the rates at which the bacteria of decay grow and multiply, but stowage in crushed ice alone cannot inhibit their activities completely

Bacteria of decay are present on the fish when caught but only in negligible numbers As at present handled on board ship after capture, however the fish become very heavily infected with these organisms As a result of this severe infection, storage in crushed ice will in general maintain fish in a really fresh state for not more than 6–7 days Important researches at the Torry Research Station, Aberdeen[1], have shown that, with care, infection of the fish after capture can be so greatly reduced that they will remain fresh in crushed ice up to a maximum of 10–12 days By greater attention to cleanliness, therefore, a marked improvement could be brought about in the quality on landing of ice preserved fish

Following upon its researches along these lines, the Torry laboratory has now issued a pamphlet[2] directing the attention of owners, skippers, and mates to certain points of importance which should be observed in the treatment of their catches if they are to obtain maximum returns from them

Many of the recommendations are of a purely common sense kind, such as minimum handling of the fish and greater attention to washing with clean water of decks, pounds, baskets and fish room fittings Certain additional precautions are also suggested, the most important and most practicable of which are the use of town supply or other clean water heated to 180° F (see below) for scrubbing all fittings, boards and baskets after the catch has been landed, and the scrubbing of the fish room with town water to which has been added 5 parts per 100 of 40 per cent formaldehyde The fish room should finally be sprayed with the same solution At sea, and before the next catch is stored, the fish room must be again hosed down with sea water in order to remove all traces of the disinfectant

While the better preservation of the catch is to be sought in greater cleanliness, attention to certain details of stowage is also recommended It is pointed out that stowed fish should be protected so far as possible from all draughts, as these hasten the melting of the ice The use of vegetable parchment for this purpose at least for the more valuable species, is advocated as being remarkably effective in preventing wasteful melting caused in this way

A noteworthy and most commendable feature of the foregoing recommendations is that they require little or no outlay of extra capital or additional running expenses, and can be immediately put into practice, with, it is claimed, marked improvement in the quality of the fish landed

Certain other recommendations are also put forward which entail the installation of special equipment and involve more radical changes in the present normal routine on board ship At all points where the fish come into contact with the ship or its fittings, it is suggested that heavily galvanised steel be used to replace or to cover the usual wood, galvanised steel baskets should be substituted for wicker ones, additional pipes and connexions should be installed on deck to facilitate more thorough washing of the fish after gutting, and a heater is advocated for providing water at a temperature of not less than 180° F

Although there can be little doubt of their theoretical desirability, it is not likely that these special and somewhat costly fittings will be quickly and generally installed throughout fishing fleets But this in no way detracts from the immediate value of the other and simpler recommendations It is to be hoped that the general distribution of these leaflets amongst them will induce deep sea trawlermen to test out the proposals on their own vessels without any further loss of time This result achieved, sufficiently enhanced returns will be adequate incentive to ensure the permanent and universal adoption of the improved methods To any less practical arguments trawlermen one and all will pay but little attention

Annual Gathering at Rothamsted

THE annual gathering of subscribers to the Rothamsted Experimental Station, held on June 20, had, this year, a special significance and there was a record attendance On this occasion, the title deeds of the Rothamsted Estate, which has now become the property of the Lawes Agricultural Trust, were formally handed over to the Trustees by Mr Walter Elliot, the Minister of Agriculture The chairman of the Trust Committee, Lord Clinton, who presided at the meeting, announced that a telegram of congratulation had been received from Lord Bledisloe, Governor General of New Zealand, a former chairman of the Lawes Trust Lord Clinton then briefly outlined the reasons that compelled the Committee to issue its recent public appeal for £30,000 to purchase the estate The land on which the building stood, and the fields containing the unique long period experiments were threatened by building developments He paid a warm tribute to Mr R McDougall and the Sir Halley Stewart Trustees, who provided £20,000, and to Sir Bernard Greenwell, Bart, whose early offer of £1,000 set a standard for the numerous private subscribers and organisations As a result, the balance was quickly obtained, and the future of Rothamsted is secure for all time

The director, Sir John Russell, said that the interest in Rothamsted is well shown by the wide spread area from which subscriptions came, and by the cosmopolitan nature of the visitors at the annual meeting He took this as evidence that the policy of Rothamsted is on the right lines the purpose of the Station is not to teach farmers how to farm, but to give them information that they can use in solving their varied problems on their own farms

Mr Elliot congratulated Rothamsted on the successful outcome of the appeal While it is a pity that an estate, which has been for three hundred years in the possession of one family, has to change hands, it is clear that no more suitable new owners could be found than the organisation Sir John Lawes set up himself An old tradition has been broken, but a new one has begun which will produce equally great results for agriculture and England The work of Rothamsted will go on at its present level, for the appeal fund has provided an unmistakable vote of confidence from the agricultural community

Prof H E Armstrong, vice chairman of the Trust Committee thanked Mr. Elliot for his remarks, and joined with Lord Clinton in congratulating the Minister on his efforts in reorganising the agricultural industry He said that agricultural scientific workers, thanks to Lawes, have solved one vital problem the production of sufficient quantity of produce The next great task is the question of quality, for if animals and human beings were properly fed there would be little or no disease

During the day the visitors were conducted around the farm and the laboratories The classical experiments on grassland, wheat, and barley were inspected, and special attention was also given to recent experimental developments

There is on the farm a number of half bred ewes with four well developed teats These are being mated to a young half bred F_2 ram, bred on the farm, also with four teats, to ascertain whether ewes with this characteristic are better mothers than those with two teats

An important investigation on the technique of animal feeding experiments was also demonstrated Its purpose is to reduce the variations hitherto associated with this type of experiment by applying the modern statistical methods of design already worked out at Rothamsted for experiments on crops An interesting feature of this experiment, which is devoted to pig feeding is that each animal is fed individually in its own trough enclosure opening off the main pen In this way all types of rations can be distributed equally over all groups of pens in contrast to the usual practice in which all pigs in a group are on the same ration

The investigations on the use of electricity in farm buildings attracted much attention Numerous farm and barn operations can conveniently be performed by electrical power and measurements are taken of the number of electrical units required as compared with the amounts of fuel consumed by internal combustion engines doing the same work This information is not, at present, available for the farmer who contemplates employing electrical power, and it is the purpose of the experiments at Rothamsted to supply it

In the afternoon the work of the laboratories was inspected, and demonstrations were given of certain investigations which have reached the stage of practical development Among these were the inoculation of lucerne, the purification of effluents from sugar beet and milk factories, methods of measuring the properties of flour doughs, and a number of problems associated with bee keeping and the grading of honey

University and Educational Intelligence

GLASGOW —The honorary degree of LL D has been conferred on the following, among others W R Cunningham, University librarian and keeper of the Hunterian books and manuscripts, Prof H M Macdonald, professor of mathematics, University of Aberdeen, Sir Harry McGowan chairman of Imperial Chemical Industries, London, Prof Frederick Soddy, professor of inorganic and physical chemistry, University of Oxford

LIVERPOOL —Dr G C McVittie has been appointed to a lectureship in applied mathematics rendered vacant by the election of Mr R O Street to the chair of mathematics in the Royal Technical College, Glasgow Dr Mary W Parke has been appointed algologist at the Marine Biological Station, Port Erin, for the coming year, and Mr R G Bruce naturalist in charge of the Station

LONDON —Prof L N G Filon has been re elected vice chancellor for the year 1934–35, and Dr George Senter, principal of Birkbeck College, deputy vice chancellor for the same period

On the occasion of the celebration of Foundation Day 1934 the honorary degree of D Sc will be conferred on Prof Karl Pearson and the honorary degree of D Litt on Dr A F Pollard

A university postgraduate travelling studentship of the value of £275 has been awarded for one year to Arthur Herbert Cook (Imperial College—Royal College of Science) Mr Cook proposes to carry out chemical research in the Universities of Zurich and Heidelberg

OXFORD —In presenting Prof A V Hill for the honorary degree of D Sc at the Encaenia held on June 20, the Public Orator, Mr Cyril Bailey spoke of his singular devotion to the study of physiology, and especially of his most accurate investigations of the conditions of muscular activity As a Balliol man he regretted that Prof Hill his fellow scholar at Blundell s, had preferred to go to Cambridge, but sometimes gifts were to be given to the Danai In conferring the degree the Chancellor, Lord Halifax, addressed Prof Hill as ' most exact of men, who have dealt so acutely with physiology, that we account scarcely any of the secrets of the human frame as foreign to you"

Among the other honorary degrees conferred was that of D C L on Sir Henry Miers

A SCOTTISH National Conference on the Place of Biology in Education' has been arranged by the British Social Hygiene Council to be held in City Chambers, Edinburgh, on October 19 The president will be the Right Hon Sir Godfrey Collins, Secretary of State for Scotland, and among the speakers will be some of the leading Scottish biologists, who will deal with biology in the school and university and in its relation to man Further information can be obtained from the Secretary General, British Social Hygiene Council, Carteret House, Carteret Street, Westminster, S W 1

Science News a Century Ago

Colonisation of South Australia

The colonisation of Australia owed much to the writings of Edward Gibbon Wakefield (1796 1862) who it has been said, brought to the subject for the first time the mind of a philosopher and statesman, equally fitted for framing a comprehensive theory and for directing its working in practical detail' Wakefield's book, Letters from Sydney', published in 1829, was followed by the formation in 1830 of the National Colonisation Society, while his book, England and America', 1833, which contained a chapter on the art of colonisation, was followed by the inauguration of a company with the title of the South Australian Association On July 1, 1834, this company held a public meeting in Exeter Hall, at which its aims were set forth, and soon afterwards the matter engaged the attention of Parliament Later in 1834, the Colonisation Commissioners for South Australia were appointed and under their auspices the first settlers left England in 1836, arriving in Australia on December 28, Capt (afterwards Rear Admiral Sir John) Hindmarsh being the first Governor of the Colony

Scott Russell's Steam Carriage

John Scott Russell (1808–82) the famous naval architect and shipbuilder who with Brunel constructed the *Great Eastern* was a student at the Universities of Glasgow St Andrews and Edinburgh and when Sir John Leslie professor of natural philosophy at Edinburgh died in 1832 he was selected to fill his place temporarily About this time he turned his attention to steam vehicles and on July 2 1834 took out a patent That year no fewer than six of his carriages were at work in Scotland The subject however was not pursued and he then turned his attention to the study of waves and the resistance and construction of ships for which he is remembered to-day

Prof Hausmann of Göttingen

On July 5 1834 Prof Johann Friedrich Hausmann the German mineralogist and geologist who occupied a chair at Göttingen sent a letter to the editor of the *Philosophical Magazine* disclaiming a statement that he had been a pupil of Mohs whom indeed he did not know though he esteemed him highly Hausmann who was born in Hanover in 1782 studied at Brunswick under Knoch and then at Göttingen under Blumenbach From 1803 until 1806 he was engaged in the mines of Brunswick in 1809 was inspector general of mines in Westphalia and was appointed to the chair at Göttingen in 1811 He made many excursions into Sweden Norway France Holland and England and wrote many works Already in 1803 and therefore earlier than Mohs he said in his letter I became a mineralogical writer building my system on peculiar views belonging to no other school I was the first who appeared as opponent to Werner assisted in the spreading of Haüy's theory and published my first system in 1809 founded on chemical composition and external character I gave in 1813 a complete Handbuch on Mineralogy

Newton's House

The *Mechanics Magazine* of July 5 1834 contained the following note We are glad to observe from the newspapers that Mr Thomas Steele has revived his laudable project for preserving the house and observatory of the illustrious Newton [in St Martin's Street Leicester Square] by enclosing it in a monumental building with a lofty dome—in the same manner as the primitive chapel founded by St Francis at Assisi in Italy is enclosed by the great Franciscan church of more modern times Steele's project never came to anything the house stood until 1913 and its site is now occupied by a fine building the Westminster Public Library on which is a tablet referring to Newton

Sir Gilbert Blane, F R S

A correspondent has pointed out in connexion with the paragraph under this title in NATURE of June 23 p 957 that Sir Gilbert Blane established in 1830 with the sanction of the Admiralty a fund for the encouragement of Naval Medical Science This fund which is vested in the Royal College of Surgeons is employed for providing an annual Gold Medal for the medical officer who obtains the highest place in the examination for promotion to Surgeon Commander.

Societies and Academies

LONDON

Royal Society, June 21 P D F MURRAY Uncoordinated contractions caused by egg white and by alterations in the cation ratio of the medium in the heart of the chick embryo *in vitro* If suitable fragments of chick embryos in primitive streak stages be explanted into the egg white of four or five day eggs there occurs a differentiation of contracting cardiac tissue The contractions differ from those seen in similar explants in plasma in lacking coordination each cell contracting independently of the others When entire hearts of 2½ day embryos are similarly explanted into egg white the coordinate beat always stops and is usually replaced by uncoordinated contractions This anarchic activity is given the provisional name of twitter It is caused by the high potassium content aided by the lower but still rather high calcium content and by the low content of sodium K MELLANBY The site of loss of water from insects An apparatus is described which will measure the amount of water evaporated from an insect and is accurate to a hundredth of a milligram The rate of loss of water from three species of insects was determined (1) in dry air (2) in air to which 5 per cent of carbon dioxide had been added and (3) in a mixture containing less than 1 per cent of oxygen In insects with a spiracle closing mechanism the rate of loss of water under (1) and (2) (which caused them to keep their spiracles open permanently) was 2 7 times that in dry air In insects which could not close their spiracles the rate of loss of water was practically the same under all conditions 2 per cent carbon dioxide is sufficient to cause insects to keep their spiracles permanently open oxygen has to be reduced below 1 per cent to have the same effect From these experiments it appears that practically all the water evaporated is lost by way of the tracheal system and that a thin integument may be just as watertight as one which is highly sclerotised P A BUXTON and D J LEWIS Climate and tsetse flies laboratory studies upon *Glossina submorsitans* and *tachinoides* It is already known that the number of tsetse flies which can be captured under standard conditions rises and falls with the season and that many of the species are sharply limited to particular types of vegetation It is thought that the limits are climatic Observations made under controlled conditions in the laboratory support those made in the field taken together the results should tend to give precision to the control of *Glossina*, which will probably be achieved by altering the vegetation and with it the micro climate

Forthcoming Events

Friday July 6

Geologists Association at 7 30 —(in the Architectural Theatre University College Gower Street W C 1)— Sir Arthur Smith Woodward Some Recent Studies of Fossil Vertebrate Animals in North America

---

Museums Association July 2–6 Annual Conference to be held at Bristol

Dr Cyril Fox Presidential Address

Discussion Folk Museums to be opened by Dr R E M Wheeler

Dr F J North 'Maps in the Museum

Dr A E Trueman Science and the Public Museum

International Ornithological Congress July 2–7 To be held at Oxford

Fourth International Congress for Applied Mechanics July 3–9 To be held at Cambridge

---

Official Publications Received

GREAT BRITAIN AND IRELAND

Society of Dyers and Colourists The Jubilee Issue of the Journal of the Society of Dyers and Colourists 1884 1934 Edited by Dr F M Rowe and E Clayton Pp xii+228+xxxv (Bradford) To Junior Members 5s Members 12s 6d , non Members 25s

Air Ministry Aeronautical Research Committee Reports and Memoranda No 1570 (I C E 884, 951) Comparative Engine Tests with Petrol and Butane By P H Stokes and F G Code Holland Pp 66+28 plates 4s net. No 1578 (Spin 159 and 175) Modern Spinning Tests of an Interceptor Fighter By A V Stephens and R H Francis Pp 17+2 plates 1s net No 1579 (T 3456) Continuous Rotation Balance for Measurement of Yawing and Rolling Moments in a Spin By P H Allwork Pp 6+3 plates 9d net (London H M Stationery Office)

The National Physical Laboratory Metrology Department. Tests on Volumetric Glassware Pp 34 (Teddington National Physical Laboratory) Free
